During the month of August, the Boston Consolidated mill treated about 550 tons of the Bligham porphyry-ores daily, which averaged 1.7% copper, yielding a concentrate assaying from 26 to 27% copper, while the extraction was about 71%, or 1% above that of June, which held the record. The August milling-costs were also lower than at any time since the plant was placed in operation, being about 56c. per ton. Four units of the mill were operated; but four more are ready and will be placed in commission as soon as the mine management supplies the ore, which will be about September 15. Treatment will then be given to 1600 tons of ore per day. Ultimately it will take care of 5000 tons; when it is expected, the costs per ton for milling will be reduced to 35c. per ton.

The Boston Consolidated is about to cut off an important item of expense by installing a Barr & Jackson centrifugal pump, adding it to the equipment of the pumping plant, and developing certain springs on its own property. At present the mill is supplied with water by the Garfield Water Co., in which the Boston Consolidated, Garfield Smelting, and Utah Copper companies are joint owners. The springs referred to will furnish all the water needed to operate the mill at full capacity, and will therefore do away with the necessity of buying it in the future, for it constitutes an important item of expense. The only cost hereafter will be that of pumping and maintenance of the pumping plant. The difference in the elevation between the pumping plant and the mill is 300 ft. vertically, and the length of the pipe-line is 4400 ft. A reservoir with capacity for 1,500,000 gal. of water is situated on the side-hill above the mill.

The lead department of the new Tintic smelter is in commission, and the initial bar of bullion was produced therefrom on August 29. This plant is equipped with four lead furnaces, and one copper furnace. The latter will probably be placed in commission about October 1. Producers in the Tintic district are manifestly interested in the operation of a smelter in the camp, as they are assured of a market for their ore, and will be free from the cost of shipment to other places for treatment. The cyanide department of the mill at the Jennie Gold Mining Co.'s property at Gold Springs, Iron county, which was damaged by a cloud-burst last July, is ready for operation. The plant has a capacity to treat 50 tons per day.

JUNEAU, ALASKA.

Developments on Chichagof Island.—New Installations at Mills Mine.

During the summer there has been considerable activity both in mining and prospecting at Kigak bay on Chichagof island, but no new discoveries of any importance have been reported. The De Groff mine, which up to this time has been the only producer, has been running continuously. The orebody which is being worked consists of two shoots, one 50 ft. long and the other 60 ft. long on a vein averaging 6 ft. in thickness. The upper adit has not been driven to the end yet; therefore, it is not known whether or not there is another shoot. The lower adit has not reached the orebody up to the present time. At the Mills property, which lies on the extension of the De Groff vein, development has been carried on actively during the summer. The work done up to the present time consists of 600 ft. of driving and 300 ft. of open-cut work. The management is preparing to install a 2000-ft. aerial tram to convey the shipping-ore to tide-water. Ore assaying $190 or more per ton is classed as 'shipping-ore,' and is sacked and shipped to the Tacoma smelter, usually by gasoline boat as far as Sitka. The remainder is thrown on the dump to await the advent of better transportation facilities or the erection of a mill. On Hirst Cove, which lies to the north, over Doolith Mtn. from Kigak bay, development is being done on the claims owned by Bernard Hirst, of Sitka. Some work is also being done on the Bahrt claims, which lie on the south side of Doolith Mtn., on what is supposed to be an extension of the Hirst orebody.

The Eagle River mine, situated about 20 miles north-west of Juneau, has been steadily producing bullion, and it is reported that the results of new exploration and development have been very satisfactory. At the Perseverance mine, in Silver Bow basin, work is being pushed on the foundation for the second hundred head of stamps, and in the meantime the first hundred has been kept working at full capacity. Assessment and development work are being done on the Denny claims in Sheep Creek basin. A tramway line is being surveyed to connect with the tramway already built up Sheep creek from the old stamp-mill. A small force of men is engaged in developing the property at Sumdum bay. The lode which has been explored yields high-grade ore, but it is very narrow. The outlook, however, is good.

The re-grinding and amalgamation plant which has been installed at one end of the 100-stamp mill of the Alaska United Gold Mining Co.'s 700-ft. mine, has commenced operation. This plant is designed to treat 50 tons per day of Douglas Island concentrate, reducing them from an average value of about $80 to less than $30. It is estimated that a net profit of $3 per ton of concentrate will be made, over that made by shipping directly to the smelter. The plant consists of one tube-mill, one 24-ft. amalgamating plate, amalgam-trap, automatic samplers, settling tanks, and storage bins.

Sinking has been resumed at the Ready Bullion mine of the Treadwell group; the bottom now is at the 1500-ft. level. This will necessitate installing a new hoisting engine, as the one in use will not be able to hoist from a deeper level.

On Chichagof Island, Alaska.
Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Sherardizing is a dry process of galvanizing, in which the articles to be coated are packed in a closed receptacle, in contact with zinc-dust. The receptable is then kept at a temperature of from 400 to 600°F. for a period of time depending upon the thickness of the coating desired, after which it is allowed to cool before being opened.

Settlement of earth embankments depends upon the material, the method of constructing the fill, climatic and other conditions. Railroad engineers commonly assume that earth embankments settle 10% of the vertical height, and make no allowance for lateral shrinkage. Rockfills occupy from 1.25 to 1.9 times as much space as did the original material in its native bed.

A pendulum to beat seconds should be 39.1 inches long. The exact length would of course vary with the latitude and the altitude. The number of vibrations which different pendulums will make in a given place in a given time is inversely proportional to the square root of their lengths. The time in which different pendulums will make a complete vibration varies directly as the square root of their lengths.

Hungarian riffles consist of cross-grooving in the bottom of a sluice, so arranged that the current of water and sand will fall over an edge into the groove, which is recessed on the up-stream side underneath the lip, thus producing an eddy in which gold or other heavy substances will be deposited, while the lighter material will sweep on with the current up the sloping down-stream side of the groove to the next lip. This old principle is now utilized on gold dredges, the riffles being made of angle-iron.

Storage batteries of the most improved design are those in which the electrodes are of sponge-lead and lead peroxide, which when immersed in dilute sulphuric acid, form a voltaic couple. Its action is the same as the ordinary primary battery, except that when it has given out all the energy that the chemicals present enable it to supply, instead of having to put in new chemicals, the cell can be regenerated by passing current into it in a direction opposite to that in which the flow took place on discharge.

Hydraulic gradient is the line to which water-levels would rise if piezometer tubes be inserted along a pipe-line, the flow through which is due to the action of gravity. For a pipe of uniform size, with no sharp turns, the hydraulic gradient is approximately a straight line. A water-main should be laid so that all points are well below the hydraulic gradient, else air will collect in the high parts and materially reduce the quantity of the discharge. If it be absolutely necessary to have a considerable portion of the main above hydraulic gradient, an air-chamber should be provided, from which the air may be exhausted as it collects.

Mill-sites are located by posting notice and staking by a substantial post at each angle. Ordinary prudence would require that the stakes be inscribed with the name of the mill-site and the number of the corner. There are no statutory regulations as to the details of such location, but their record should conform to the requirements applicable to the record of all classes of claims. In other words, where any record whatsoever is essential to either original claim or a subsequent conveyance, it must contain a description sufficient to identify the land intended, to be described. The shape of the claim is immaterial; provided its area does not exceed five acres.

The U. S. standard gauge for sheet and plate iron and steel is based on the fact that a cubic foot of iron weighs 480 lb. A sheet of iron one foot square and one inch thick weighs 40 lb., or 640 oz. Therefore a sheet of iron one foot square and 1/16 in. thick weighs one ounce. The scale has been arranged so that each number represents a certain number of ounces in weight, and an equal number of 640ths of an inch in thickness. The numbers range from 0000000, which weighs 320 oz. per square foot and is 0.5 in. thick, to 38, which weighs 4 oz. per square foot and is 0.00625 in. thick. An act of Congress requires that, after July 1, 1893, this gauge shall be used in determining the duties and taxes levied on sheet and plate iron and steel. Unfortunately, neither this nor any other system has come into universal use in this country, and as a result much confusion is entailed. The decimal system is used by a number of manufacturers, and is recommended by a joint committee of the Am. Soc. M. E. and the Am. Ry. M. M. A. The numbers of this system correspond to the number of thousandths of an inch in the thickness of the sheet.

Sea-water has been successfully used on a practical scale in Chile for making up cyanide solutions. In that particular instance the extraction of the gold was high and the consumption of KCy well within limits of commercial success. The composition of the ore, however, must have been unusually favorable. While sea-water is inert toward potassium cyanide, chemical complications would easily result in any but a very simple ore. As an example, the presence of decomposing pyrite would yield ferrous sulphate which would promptly react with the salt in the sea-water, as follows:

\[
\text{Fe}_2(\text{SO}_4)_3 + 6\text{NaCl} + 30 = \text{Fe}_3\text{O}_4 + 3\text{Na}_2\text{SO}_4 + 6\text{Cl}.
\]

Not only is an energetic cyanide liberated by the above reaction, but exhaustion of the oxygen ensues, which is essential in the solution of gold, as shown by the classic Elsner equation. Under the circumstances, polarization would occur at so early a stage of the treatment that the anticipated extraction would be very low, and the cyanide consumption extraordinarily high. Before using sea-water a very careful study of a quantity of ore reserves sufficient for a long campaign, should be made.
Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

Fee-Simple Tenure of Mining Property.
The Editor:

Sir—In the editorial in your issue of August 29 on the ‘Fee-Simple Tenure of Mining Property,’ certain questions are raised which perhaps admit of further discussion. You say, ‘Here, at bottom, rests the great difference which gives paramount advantage in point of security to a title in fee-simple. It is a title which protects the man, whereas under the concession-system the man must protect the title.’ The question at once arises whether it is to the interest of society to protect the man rather than the title under the supposed conditions, namely, of refusal to abide by the conditions of a lease. If the man is willing to abide by such conditions, evidently leasehold affords as good title as fee-tenure. If he is not willing to do so, why should he be protected? As you suggest, the answer touches the foundations of our social organization. In the years past, Americans have preferred to ‘protect the man,’ whether he let his property lie idle, wasted the bulk of his ore, or did any of those things which presumably would be forbidden in a lease. This, I believe, has been because there has been an excess of property. We have, in a way, been living on an inherited surplus, and what one man wasted, devoted to improper uses, or fenced off and kept from development, did not seem to be taken from anyone else. There was no pinch of poverty and accordingly no discontent. Each took what he would and did as he pleased. The result was the development of the magnificent individual initiative which has contributed so much to American success. Such a spirit has been worth much, and, if it were possible by maintaining the fee-tenure system to maintain this spirit, it would probably be worth the price. But, as pointed out by so accurate an observer as Bismark as early as 1868, our institutions must face a wholly new trial when our surplus begins to be exhausted. When there are no more farms to be taken up, the non-use of agricultural lands by any owner becomes a matter of general concern. When the forests begin to disappear, it is a grave question whether we can afford to continue to protect the title of a man who destroys his forests and provides for no renewal. When copper becomes scarce, society can hardly afford to protect the man who wastes copper. In other words, changing conditions, and particularly the exhaustion of our surplus, must change our attitude. Actually the change occurs whether we will or not. Under our policy of individual ownership a single company now has a monopoly of the coking coal of the inter-mountain country, and a small group of companies holds the anthracite fields of the East. Are there any reasons to suppose that under a leasehold system individual initiative will be more repressed than under a system of large private monopolies? Opinions may differ, but personally I doubt if there are.

In municipal public utilities, where there are many analogies, we are meeting the situation by the development of a system of leases, or ‘franchises,’ giving privileges for a term of years, and permitting periodic readjustments to meet changed conditions. While there have been many scandals, and while many objections may be urged against such a plan, it seems to me to be the only ultimately feasible one as regards our mineral resources. The time for its application to different industries must be studied with care, holding on to the individualistic system in each case as long as may be. There are reasons for believing that the time has already arrived for applying the new system to the remaining public coal-lands, and there are some suggestions at least that the same is true of mineral lands in general. Whenever individual prospecting fails to bring in new camps and orebodies as fast as the market demands metal, when organized scientific prospecting of large territories becomes necessary, then, I believe, it will be advisable to adopt some form of concession covering large tracts, but subject to periodical readjustments to meet changing conditions; in other words, a leasehold system. To my mind it is not a question of whether such a system would prove as stimulating to the individual as that under which our grandfathers did live, but whether it would not be more stimulating than any other under which our grandchildren would otherwise live. This, as you say, is no longer an academic question, and a right solution demands the best thought and effort of all of us.

Professional Ethics.
The Editor:

Sir—'Constant Reader,' in your issue of August 29, emphasizes, by citing direct cases, two of the many nice points in professional ethics which are stumbling blocks to the inexperienced engineer. Delicate situations arise in the life of an engineer which require diplomatic handling, and happy is he who can keep his head above the waters of unjust criticism. Discussing the questions asked in a general way, I hold that, inasmuch as the young engineer is particularly well informed as to the condition of the mine, mining costs, and other facts essential for the expression of an intelligent opinion, he is committing no breach of professional etiquette if he advises his client of the facts, using the information he has gained while formerly in the employ of the company which is now soliciting aid from his client. A hurried trip through the mine previous to the giving of advice, to convince the engineer that conditions have not changed, might be advisable, and would be sufficient to support his statement. In all cases the engineer must be sure of his premises before expressing his conclusions. Advice should only be given on certain knowledge. The tendency of the times is to conduct mining operations on strictly business principles; the open-door policy is fast coming into favor, so that in most cases a would-be investor is able to get reliable information concerning the property. The size of the investment,
the amount of money involved, is not the vital question; the point is, is it a reasonable venture? Should the engineer know positively that the business methods of the company are subject to criticism, or should he be in possession of reliable information that the mine is exhausted, or that its future is doubtful, when directly confronted with the question, he is at liberty to reply. An evasive answer or refusal to reply might be misconstrued and end disastrously to both himself and client. If he from positive knowledge condemns the property, he is benefiting the mining community directly, and his client particularly, by expressing himself, and if he is equally well assured that the property has merit, and that its affairs are being properly administered, he will never be censured for giving it a boost.

I do not indorse the widespread publication of information given in confidence, but as a doctor to a patient, specific knowledge can conscientiously be used in making out the prescription. First be sure of your premises, then have the courage to express your convictions. But at all times act honestly and honorably with yourself, your former employers, and present clients.

Los Angeles, August 31.

An Automatic Ore-Sampler.

The Editor:

Sir—In considering the merits of automatic sampling-machines, it should be remembered that the danger of taking out an uneven sample (unless the ore is very fine) is caused by the larger pieces of ore striking together at the entrance of the slot-cup and rebounding while the fine ore is allowed to pass on to the sample. This continued loss of coarser ore (the coarser, the greater the discrepancy) causes quite a variation in the sample.

I described a sampler in the Mining and Scientific Press, November 28, 1903, which had more than one arm extending with buckets on the end; the idea being to use anywhere from one to eight buckets, depending on the value of the ore and proportion of sample desired. As there has been a great revival in mining in Nevada since that article was written, it may be of interest to ore shippers to again describe the method of hand-sampling adopted and some of the dangers of automatic sampling of rich ore.

In custom-samplers, whether independent or in connection with a smelter, it is best to have every department simple, and with as little mystery as possible, so that the shipper will have his ore in plain sight all through, from the time it is weighed until he receives a portion of the pulp sealed, with the sampling-works’ seal. I have heard of cases where shippers also put their seal on the umpire sample before it is set aside. In this way he can make a perfect check on the assays of the purchaser, and, if he is not satisfied with the methods of sampling, may make his complaint before the sample is completed.

The method of hand sampling usually adopted by the smelters is as follows: first, crush the ore to reduce all the lumps below a certain size; then take out every third, fifth, or tenth shovelful for a sample, as the ore is wheeled away to the storage bins. The proportion taken for a sample depends either upon the size of the lot to be sampled or the richness of the ore (in fact, the entire bulk of small lots of rich ore is often treated as a sample). Every third shovelful of this sample is then taken and passed through a set of rolls; the rolls are then set up much closer, and half of this sample, by taking out every alternate shovelful, passes through again. This reduced sample is now taken to the sample-room, which is enclosed with windows for light, and enables the shipper to watch the work. The floor where the sampling is done is covered with steel plates. The sample, as brought from the rolls, is deposited in two piles, then coned into one cone, and carefully flattened out and cut into four quarters, two quarters being taken for the sample, and two quarters being rejected, care being taken to alternate, that is, if the first two quarters taken up in a wheel-barrow are rejected and the remaining two quarters are re-coned for a sample, the next time the sample is coned and quartered, the reverse is done by re-coning the first two quarters lifted, and rejecting the remaining two quarters on the plate. This is done in order to avoid any chance of favoring either the shipper or the purchaser. At several smelting works where they adopt hand-sampling a divider is used, upon which the ore is thrown when forming the cone, so that when rejecting two quarters and re-coning the other two, a clean division is made, and there is no danger of taking out too much or too little for the first two quarters removed. This cone-centre divider is a simple contrivance, being nothing more than a cross, made of narrow strips of sheet steel set on edge and crossing each other
at right angles. After the sample is reduced in weight to about fifteen to twenty pounds, it is put through an ordinary sample-grinder, which reduces it to a fine powder. From the grinder it is taken in covered buckets to the assay office, where the assistant assayer thoroughly mixes it, by continuing the operation of coming and quartering, until the sample is reduced in quantity to about 40 oz. Although at this stage, when the sample is so extremely fine, cutting down with a raffle is quicker and just as accurate. This 40-oz. sample is then passed through a 100 or 120-mesh sieve, by grinding the pulp, which is too coarse, on a smooth cast-iron bucking-board, with a heavy muller. Should any scales of native gold or silver be caught they are cupelled with a little lead, and weighed; the pulp from which the scale was seived is also weighed, the percentage-value calculated, and added to the assay. After the pulp is all through, the sieve, it is again thoroughly mixed and put into three different samplesacks, one to be assayed at the works, one to be sealed and set aside for umpire, in case an umpire should be called for, and one to be sealed and handed to the shipper, or mailed to him. Settlements are made as soon as the assays are compared between the shipper and the smelter, or else the settlements are forwarded on the smelter’s assays, for nearly the full net value of the ore; and corrections are made afterward. If the shipper finds any material difference between his assay on the smelter’s pulp and the assays of the smelter, a re-assay is called for by both parties. If these repeated assays do not satisfactorily agree, then some reputable assayer is called on as umpire who shall be mutually agreed upon between the shipper and purchaser, and his results are accepted as final.

The same methods as described above are followed in the sampling of concentrate, except that no crushing or rolling is necessary. In some sampling works and smelters, samples are first taken out by hand-shoveling, then rolled, and completed with automatic samplers.

To the owners of mills handling none but their own ore the importance of expensive hand-sampling does not appeal, but to the shipper it does. I admit that hand-sampling is expensive, and one has to depend upon laborers being careful in taking the sample-shovelfuls from the same place they take the rejected portion; and for this reason I propose a compromise by taking out the first sample automatically, and then completing the sample by hand-labor, as described above. To do this and take samples of both coarse and fine ore as it comes from the crusher in plain sight, economically and with as little danger of salting as there would be with shovel-sampling. I have outlined the following system: the ore as it is received after being weighed can be dumped or shoveled into a crusher; from the crusher it drops into an ordinary ore-car, by which it is conveyed over the bins or mixtures. Between this ore-car and chute from the crusher, pass the buckets of the sampler, so arranged as to time, size, and number, that an average sample of the coarse and fine is anywhere from one-twentieth to eight-twentieths, no matter how coarsely the ore is crushed. If a larger portion is desired for a sample, it would be just as well to take out the entire sample by hand, re-crushing at different stages to make the ore finer as the quantities are reduced. The method of hand-sampling for very rich ore appeals to any one interested in sampling, as being the most accurate and safest way. When sampling an extremely rich ore, it is well to check the sample. If one makes duplicate samples with an automatic sampler, and the work has been done imperfectly, on account of the ore being too coarse or the machinery being full of leaks and places to catch dust, the error is only repeated. In hand-sampling, a very fair way is to cone the entire lot or sample, then divide it by taking two opposite quarters for one sample, the two remaining quarters for a duplicate sample, and then take the average of both samples for settlement. Automatic sampling is certainly the cheapest and best method for mills and smelters treating their own ore. But in the sampling of rich custom ore the saving of a few cents per ton is poor economy compared with the danger of salting the sample and not giving satisfaction to the shipper.

San Francisco, August 17.

**Foothill Copper Belt of the Sierra Nevada.**

The Editor,

Sir—As indicated by his letter in your issue of July 11, John A. Reid seems to have taken to heart my criticism of his paper under the above title in the issue of March 21. Perhaps I looked too much upon the copper deposits of the ‘foothill belt’ as commercial propositions, rather than as interesting studies in ore genesis. That I was not unreasonable in fearing that the paper might mislead the general reader will be evident from a brief review of it. Mr. Reid starts with the avowed intention of “beginning a complete study and description” of the entire foothill belt, but later says that “the southern half, which is probably the more important, is the one forming the main subject of this paper.” Then he proceeds to describe in general terms the geology of the entire region, falling back on a few prominent mines, such as the Campo Seco, Copperopolis, Pocahontas, Great Northern, Cavan, and Napoleon as illustrations. He makes a number of comprehensive statements, such as, “The copper belt is characterized by a small amount of secondary ore, either oxidized or sulphide.” Then he describes in some detail the Copperopolis and Pocahontas mines, after which he announces, “The conclusions to be drawn from the facts presented in this paper are not many, but they are important.” Among these facts are comprehensive statements such as the one previously quoted. Although he disclaims the intention of writing other than a preliminary paper, the whole tenor of it implies a wide acquaintance with the belt, and, coming from a man of his position and attainments, it is bound to mislead the unwary.

I have not intimated that Mr. Reid’s paper “was based upon the examination of but one deposit,” but of “only one of the many types of deposit repre-
sent" in the belt, a type in which the secondarily enriched sulphide-zone is very shallow and unimportant, and in which some of the primary sulphides constitute ore in the commercial sense.

I hope my criticism will not discourage Mr. Reid from continuing the publication of his studies on the foothill belt. We need all of the knowledge he possesses and will gain in the future regarding the ore deposits of the belt by having his data.

In *The Engineering and Mining Journal* Herbert Lang published a paper, in three parts, under the title of 'The Copper Belt of California,' in which he gives an interesting description of the economic features, geology, ore deposits, precious-metal contents, methods of ore-treatment, and the history and extent of the more important mines and prospects for future operations in the foothill copper-belt. The writer evidently had an intimate knowledge of the Fresno mine, a rather wide partial acquaintance with many other important properties, and had extensively consulted the literature on the copper-belt. It is not my purpose to criticize the article in general, but I wish to call attention to certain phases of it. In writing of the sulphides occurring in the belt-mines, Mr. Lang says that pyrite and pyrrhotite are the prevailing minerals, the former characterizing the northern part of the belt, and the latter the southern part. "The copper mineral is chalcopyrite almost exclusively in these sulphide masses, chalcopyrite being totally absent, and bornite only occasionally reported." Mr. Lang is evidently describing only the primary sulphides of the belt. Although his paper pretends to be a comprehensive discussion of the entire belt, he fails to mention the many places where the secondary enrichment process has taken worthless primary sulphide rock and made commercial ore by altering it and adding to it chalcocite, bornite, and probably in places secondary chalcopyrite. Hence, when he says in his general conclusions that "it will have been gathered that the deposits conform closely to a single type, it is evident that he has laid himself open to the charge of basing conclusions on imperfect acquaintance with the facts, and of making them too general. Mr. Lang's paper would be more valuable if he had thrown together all the evidence concerning a single mine, as, for instance, the Fresno mine, and then drawn a conclusion to apply to it alone, treating each mine with which he may be intimately acquainted in a similar manner.

The term 'ore,' as used by such writers as Lang and Reid, is likely to mislead the untechnical reader, who generally thinks of 'ore' as something possible of profitable exploitation. I agree with Mr. Reid that in the country southeast of Copperopolis the value of most of the mines depends upon whether or not any large part of the primary sulphides is ore in the commercial sense, but I go farther in asserting that at most properties it is not. Perhaps the primary sulphide rock of the Fresno mine, 70% of which is pyrrhotite, carries more chalcopyrite than any other large body of pyrrhotite on the belt, but Mr. Lang concedes that it contains hardly 2% copper. Where the principal primary sulphide is pyrite there is more chance for commercial ore.

In conclusion, I will repeat that the purpose of my criticisms is not to discourage discussion of the foothill belt. Mr. Reid has given us a detailed discussion of the Copperopolis and Pocahontas ore-bodies, and from Mr. Lang's paper we can get a fairly good description of the Fresno mine; now give us similar descriptions of several hundred other mines and prospects on the belt and we will be ready to formulate general conclusions.

Oscar H. Hershey.

Reno, Nevada, August 17.

A Theory of Ore Deposition.

The Editor:

Sir—Referring to J. E. Spurr's able article on 'A Theory of Ore Deposition,' and his letter in your issue of May 16, a point has been raised, upon which I think several, like myself, may also 'want to be shown.' Of the many who seek for "veins traversing the eroded rocks of rich placer regions," how few shall find! In the same issue I note that, notwithstanding a placer production of $37,000,000 in the Seward Peninsula, there has been but one successful attempt at lode-mining.

Where are the lodes corresponding to the vast tin placers of Malaysia? Would erosion have been very active in jungle and swamp? Personally, I have failed to find lodes commensurate with the gold placers of South America. Conversely, have there been placers of sufficient extent accompanying the lodes of Cornwall, Mysore, South Africa, or West Australia to justify the erosion theory? Will a majority of your prospector readers admit an all-embracing unfilled fault-channel theory, however much the root-deposit may appeal to us! Mr. Spurr jettisons the descending water theory; even the seawater solution returns to the depths of oblivion. Why not jettison the veins? Can the metals have condensed out of vapor emanating from barely perceptible cracks, such as cleavage-planes in slate? Is it not a fact that the gold of placers seldom if ever occurs in quartz, and how does the erosion theory satisfactorily account for nuggets? I confess myself puzzled.

Jose T. Pryor.

Buenos Aires, Argentine Republic, July 11.

Pig iron production in the United States during 1907 amounted to 25,781,361 long tons, as compared with an output of 25,307,191 tons in 1906, and of 22,992,380 tons in 1905. The small increase shown by 1907 over 1906 is due to the falling off in demand and production during the last quarter of the year. If the output of the first half of the year had been maintained, 1907 would have shown a total production of about 27,000,000 tons. The production of Bessemer steel ingots and castings in 1907 was 11,867,549 long tons, against 12,275,830 tons in 1906, a decrease of 608,281 tons. The total production of open-hearth steel ingots and direct castings in the United States in 1907 was 11,549,088 long tons, against 10,980,413 tons in 1906, an increase of 568,675 long tons, or over 5.1 per cent.
### MILLING PLANT OF THE MONTANA-TONOPAH MINING COMPANY.

Written for the *Mining and Scientific Press* by G. H. Rotherham.

The reduction of silver ores by wet milling and cyaniding, which has been studied to good purpose in Mexico, has had a comparatively limited field in this country. Doubtless the best practice is to be found at Tonopah, Nevada, where three well equipped mills are now successfully treating silver ores. The latest of these, the Montana-Tonopah Mining Co.'s plant, designed and erected under the supervision of the consulting metallurgist of the Company, F. L. Bosqni, and equipped by the Allis-Chalmers Co., possesses certain unique features which may be considered innovations in the metallurgy of silver ore. The ore is a gold and silver-bearing sulphide. The chief gangue-mineral is quartz, the vein-matter being a quartz replacement of the andesite. In the milling-ore the proportion of gold to silver by weight is 1 to 100. Some of the gold is undoubtedly free, the remainder being associated with the silver in the sulphide. The prevailing silver minerals are stephanite and polybasite; while beautiful specimens of ruby silver have been taken from the richer portions of the mine. Lead, copper, and zinc also occur in small quantity.

The ore, as it comes from the mine, is delivered to a 200-ton steel bin, which stands directly in front of the head-frame and adjoins the primary crushing plant. From this bin the ore is fed through a counterbalanced gate to a No. 5 K Gates gyratory breaker, which reduces it to 2-in. size. Thence it passes to a No. 5 B Gates bucket-elevator that discharges into an iron-frame revolving screen with one-inch perforations. The oversize from this screen is re-crushed in two No. 3 D Gates breakers to 1-in. size, this product then joining the undersize from the screen and passing to a 14-in. belt-conveyor, which conveys the ore to the mill-bins. This belt is 190 ft. long, and operates at an angle of 12°. It discharges onto a horizontal belt extending the length of the bins, the latter being provided with a tripper for distributing the ore. The crushing plant has a capacity of 25 tons per hour, and is operated only during one 8-hr. shift. From the bins the ore is delivered by eight suspended Challenge feeders to a battery of 40 stamps. The stamps weigh 1050 lb. and fall 100 times per minute through a 7-in. drop. The battery is the three-post, back-knee type, with wooden mortar-blocks, composed of 2-in. planks solidly spiked together and set on rubber concrete. The mortar is the Allis-Chalmers 'Homestake' narrow pattern, with extra heavy base. The battery is arranged in eight separate units, operating independently. The main counter-shaft rests low on the battery-sills, admitting of the prompt shut-down of any unit without hanging up the stamps individually. The shoes are of chrome-steel. The dies are made at a local foundry, and consist of 35% car-wheel scrap, 25% powdered manganese, and the remainder of chrome scrap. These dies give good satisfaction, whereas the chrome-steel dies were found to 'cup' badly.

The ore is crushed in cyanide solution through 20-mesh woven-wire screen, with the diameter of wire 0.016 in., and an aperture of 0.0173 in. The strength of the circulating mill solution is 0.13% cyanide of sodium. The average size of the crushed battery pulp is shown by the following screen analysis:

<table>
<thead>
<tr>
<th>Screen Size</th>
<th>Material Passing</th>
</tr>
</thead>
<tbody>
<tr>
<td>20-mesh</td>
<td>96.8%</td>
</tr>
<tr>
<td>20-30 mesh</td>
<td>2.5%</td>
</tr>
<tr>
<td>30-50 mesh</td>
<td>0.7%</td>
</tr>
<tr>
<td>50-100 mesh</td>
<td>0.2%</td>
</tr>
</tbody>
</table>

From the battery the ore goes to eight 24-in. cone-classifiers, with 50° sides. The slipot-discharge feeds eight Willey concentrators, the slime and fine sand-overflow joining the main pulp-stream after concentration. The whole mill-stream is then elevated to two Dorr classifiers for de-watering and further classification, preparatory to tube-milling. The Dorr machines are doing satisfactory work, but, as manufactured, were too lightly constructed, and had to be extensively reinforced. The best consistence of pulp for tube-mill purposes was found to be about 45% moisture. The excellent work done by these classifiers in separating a sandy product is shown in the following sizing tests:

<table>
<thead>
<tr>
<th>Screen Size</th>
<th>Material Passing</th>
</tr>
</thead>
<tbody>
<tr>
<td>20-mesh</td>
<td>70%</td>
</tr>
<tr>
<td>20-30 mesh</td>
<td>20%</td>
</tr>
<tr>
<td>30-50 mesh</td>
<td>10%</td>
</tr>
</tbody>
</table>

It is worthy of note that 70% of the pulp entering the mills is coarser than 100-mesh, and that the slime has been almost completely separated.

### SLIME OVERFLOW FROM DORR CLASSIFIERS.

</tr>
</tbody>
</table>

The two tube-mills in use are the Allis-Chalmers, spur-gear driven, trunnion type, 5 by 22 ft., lined with 4-in. silex blocks. They make 27 r.p.m. The initial starting-load for one mill requires 60 hp., while both mills in simultaneous operation take 85. Each mill is now re-grinding 52 tons per 24 hr. This is the safe limit for this ore, considering the fineness of pulp desired for the best economical work in the cyanide plant. The size of pulp issuing from the tube-mills is as follows:

<table>
<thead>
<tr>
<th>Screen Size</th>
<th>Material Passing</th>
</tr>
</thead>
<tbody>
<tr>
<td>20-mesh</td>
<td>80%</td>
</tr>
<tr>
<td>20-30 mesh</td>
<td>20%</td>
</tr>
<tr>
<td>30-50 mesh</td>
<td>10%</td>
</tr>
</tbody>
</table>

The pulp from the tube-mills, after proper dilution, is re-classified in two 48-in. cones with 50° sides. The underflow from these is returned to the mills; the overflow joins the stream from the lower ends of the Dorr classifiers, and passes to three 8 by 54-in. Frenier sand-pumps, which elevate it to two thickening-cones, preparatory to secondary concentration.
on Frue vanners. This pulp, representing the final re-ground product, shows the following distribution of sizes:

The Frue vanners, though not ideal slime-concentrating machines, do good work on this fine product. The concentrate from the Willeys and vanners is removed by traveling buckets to a drying-house adjoining the mill, where it is sacked for shipment to the smelter. From the lower concentrating floor the whole re-ground mill-pulp goes to the cyanide plant for treatment by agitation. All cyanide tanks are made of redwood, excepting the Hendryx agitators. These are constructed of Oregon fir, which, in my opinion, is inferior to redwood for cyaniding purposes. The mill-pulp, containing six parts of cyanide-solution to one of ore, is fed alternately to the centre of three settling-tanks 30 ft. diam. by 10 ft. deep at the centre, with a false-bottom sloping 12°.

These tanks are provided with leveling rim, overflow launderers, and decanting apparatus. By means of a series of decantations, the pulp is reduced to the proper consistence for agitation. Every twelve hours 75 tons of pulp, the contents of one settler, are transferred by a 6-in. Morris centrifugal pump to two of the agitators. There are six Hendryx agitators in use, 17 ft. diam. It requires 6 hp. to agitate a charge of 35 tons of ore (dry weight). The pulp in the agitator has a specific gravity of 1.28 to 1.32. A 0.2% solution of NaCy is used, and 0.3 lb. lead acetate per ton of ore. The agitation is continued for thirty-two hours. The pulp is then drawn through the same pump as mentioned above, and raised to a pulp-storage tank, 30 ft. diam. by 17 ft. deep, provided with stirring-arms making 8 r.p.m. From this tank the pulp is drawn as required into the Butters filter-boxes.

The Butters plant consists of two redwood boxes, of four compartments each. Each box contains 72 filter-leaves. Pulp and solutions are handled by an 8-in. Morris centrifugal pump, and a 12 by 10-in. Gould duplex vacuum-pump. The solution from the

Butters filter is re-filtered in a 30-in. frame filter-press, whence it flows to the precipitation tanks. There are three of these, 14 by 14 ft. The zinc-dust is added as an 'emulsion' from a small feed-cone, and passes directly into the suction of the pump, which raises the solution to the Merrill precipitation-presses set up in a separate building, 100 ft. above the precipitation-tanks, and immediately above two 28 by 8-ft. solution-storage tanks. These two presses have triangular-shaped plates, 48 in. on edge. There are thirty plates in each press, with frames spaced 2 in. apart. The solutions are raised by a 5 by 6-in. Aldrich triplex pump. From the presses the barren solution runs to the storage tanks, whence it passes into the general mill-circulation. The present method is to draw from the circulating mill-supply of solution the quantity required for agitation purposes. This amount is brought to the required strength in the agitators, and, after precipitation, it passes again into the mill-circulation; so that there is really but one solution used throughout. The value of the mill-solution is kept low by precipitating about 150 tons of it daily. That portion of the mill-solution which

Zinc-dust precipitation, as used by C. W. Merrill at the Homestake plant, South Dakota, and elsewhere, has been satisfactory in the practice at Tonopah from the first. It has the advantage of compactness, low cost for labor, and security from theft. The helper who tends the solution and water pumps gives a portion of his time only to the simple manipulation of the process. In estimating the cost of precipitation, I have not included the cost of raising the solution to the presses, inasmuch as this would have to be raised in any event for purposes of circulation; and the additional work on the pump imposed by the presses themselves may be disregarded, as the pressure at the presses never exceeds 8 lb. per square inch, and reaches this point only just before the

Montana-Tonopah Mill, Tonopah, Nevada.
clean-up, when the frames are loaded.

The precipitate is sacked and shipped by express to the smelter. It was found, by careful calculation, that the high cost of fuel, fluxes, and labor would not justify refining this product on the ground, although an average sample of 114 lb. refined experimentally without acid treatment yielded 966.9 oz. (Troy) bullion, of a total fineness of 946.39. The following figures refer to a period of eight months, from October 1, 1907, to June 1, 1908, during which interval 34,766 tons of ore was treated, and 95,657 tons of solution precipitated.

</tbody>
</table>

Total: $4,153.82

For cleaning up the two presses, twice a month, it requires the services of four men for one shift of eight hours, or $256 for eight months.

**Summary:**

- **Per ton of solution**
  - Zinc-dust: 33,903 lb. at 8.2c. per lb. $2,780.00
  - Filter cloth: 1,688 yd. twill, at 34.25c. per yd. $413.82
  - Labor: one-third time of one man, at $4 per 8-hr. shift $60.00

Total: $4,153.82

- **Per ton of metals precipitated and treated:**
  - Cost of precipitating: $0.0949
  - Cost of cleaning up: $0.0286

Total: $0.0945

- **Per oz. fine solution:**
  - Cost of precipitating: $0.0119
  - Cost of cleaning up: $0.0073

Total: $0.0192

The efficiency of the precipitation is shown by the following figures, giving average assays in the precipitation of 95,657 tons of solution:

- **Heads, Tailing, Heads, Tailing**
  - Gold oz.: 2,986.31
  - Silver oz.: 390,715.36

**Strong solution:**

</tbody>
</table>

*Excepting the month of March, 1908, when, owing to a series of breakages in a poor quality of twill-filters, the tailing from weak-solution precipitation averaged 0.24 oz. silver, this average stands 0.02 oz. above normal.*

For these eight months the average consumption of zinc-dust was as follows:

- **Consumed per ton of ore treated:** 0.978 lb.
- **Consumed per ton of solution precipitated:** 0.359 lb.
- **Consumed per ounce of metals precipitated:** 0.115 lb.

The total fineness of the precipitate, as taken from the presses, has ranged between 414 and 688, the average for the eight months being 517, or 51.7% precious metals. This product ranges between 12 and 20% zinc-content, and 10 to 15% silica. The presence of the latter ingredient is due to the extreme difficulty of completely clarifying the mill-solution before precipitation. To the eye these solutions appear perfectly clear, but they carry a small amount of solid matter, which is caught in the precipitation presses. A preliminary filtering system is now being installed, which will eliminate a great part of the silica, and considerably improve the grade of the precipitate.

The cost of tube-milling from October 1, 1907, to June 1, 1908, works out as shown below. A 4-in. lining lasted from August 20, 1907, to April 20, 1908, or exactly eight months. During that time 31,835 ton was crushed by stamps, and 68% of this, or 21,511 tons, was re-ground.

- **Cost of power:** 85 hp. for two mills, at $8, or $5400 in eight months.
- **Pebbles:** 70,860 lb., at $50 per ton, or $3500 in eight months.
- **Silex lining:** cost for two mills, using imported cement at $12.48 per bbl., $2216.92.
- **Labor:** one-half of one man's time on each shift, at $4, $1140 in eight months.
- **Maintenance and repairs:** on mills and Dorr classifiers, $79 per month, or $892 in eight months.

**Summary of Cost per ton of ore precipitated**:

<tr>
<td><em>This lining was composed of 2 ½-in. blocks set on edge to make a 4-in. lining, as there happened to be a large stock of the thinner bricks on hand. This made the lining unusually expensive. The mill was shut down 11 days for re-lining. The old lining wore down unevenly, being less worn at the tail-end of mill. The average thickness, when chiselled off from the shell, was about ⅛ in. in places the thin cement-holding had worn down to the shell of the mill.</em></td>
<td>$1,116.46</td>
</tr>
</tbody>
</table>

The cost of filtering by the Butters process for the months of March, April, and May, 1908, was:

- **Labor:** 1 man per shift, at $4, with occasional extras.

- **Maintenance and repairs:** on filter leaves, filter-boxes, and pumps.

- **Acid:** hydrochloric acid, for washing leaves.
- **Power:** 42 hp. for operating circulating-pump, vacuum-pump, and stirrer in pulp-tank, at $8 per hp. per month.

**Summary of Maintenance Costs**:

<td>oz.</td>
<td>oz. % % %</td>
<td></td>
</tr>
</tbody>
</table>

- Gold: 15.54 oz., 0.0053 oz., 23.5 oz., 97.55, 85.5, 85.75
- Silver: 14.97 oz., 0.004 oz., 23.5 oz., 94.30, 84.6, 87.49

Of this extraction approximately 40% is obtained by concentration, and the remaining 50% by cyanidation.

**Coke production** in the United States in 1907 amounted to 40,779,564 short tons, valued at $111,539,126, a total that passes all previous records in the history of coke-making in this country, being nearly double the output of 1900, and more than three times that of 1897. The increase over the production of 1906 was 4,378,347 short tons, or 12.02% in quantity, and $19,931,092, or 21.76% in value. The average price per ton at the ovens, $2.74, is greater by 22c than the 1906 average, and is the highest reported in the 28 years during which statistics of coke production have been compiled by the U. S. Geological Survey, exceeding by 11c. the maximum rate previously obtained in 1873.

**Alumina in silicates** is subject to unexpected error in analysis, as shown by Hinrichsen. On decomposing silicious minerals with HF and H₂SO₄ and subsequently conducting the analysis on the silica-free residue, a deficiency in Al₂O₃ was noted, which was found to be due to partial volatilization of the Al as a compound with fluorine. Some fluorine also was retained in the mineral.
THE NATION'S DEPENDENCE UPON NATURE.

Written for the MINING AND SCIENTIFIC PRESS
By GEORGE OTIS SMITH

*President Roosevelt's State papers have again and again contained stirring appeals to the lawmakers to make adequate provision for the conservation of the nation's natural resources. No other Chief Executive since Washington has given equal prominence to this sort of practical statesmanship. He has seen clearly that American natural wealth is not inexhaustible. The President's well-considered appeal should arouse a new type of patriotism no less than did Lincoln's call to arms inspire a new devotion to the nation. It was not a frenzied alarmist, but a hard-headed man of science who wrote that "future historians will date the end of barbarism from the time when generations begin to feel that they rightfully have no more than a life-estate in this sphere, with no right to squander the inheritance of their kind." The reform that is so sorely needed must gain its motive-power not from the well-intentioned enthusiasm of the few, but from the well-informed intelligence of the many. The campaign for conservation must be one of education. The United States leads the world in every important form of natural wealth, whether it be the product of the farm or of the mine. Our wheat crop forms 21% of the world's harvest, our corn crop 78, and our cotton crop 82%. So, also, in the matter of live stock, our herds and flocks comprise 17% of the world's grand total. To take the more important minerals, our output of coal is 40% of the world's production, of copper 50, of iron-ore and oil at least 60%. The increase in our per capita production and consumption of natural resources perhaps furnishes the best index of the increasing dependence of the nation upon its natural resources. At the outbreak of the Civil War the per capita consumption of coal in this country was only a little over one-half ton; in 1900 it was 3½ tons; but in 1907 the consumption had increased to 5½ tons. In 1850 our per capita consumption of lumber was 250 board feet; today it is undoubtedly close to 500 board feet. In 1870 our per capita production of iron-ore was 160 lb.; last year it exceeded half a ton.

The most valuable of all natural resources are water and soil. No more attractive field for increasing the country's available wealth lies before us today than that of determining the possibilities of our rivers and streams. Here we shall find the solution of the problems of improved inland water-transportation, successful agriculture, cheap power-development, and adequate protection from floods. The rivers of Maine now turn wheels that furnish a total of somewhat more than 210,000 hp., and with proper storage facilities the full development of her water-powers might yield 1,200,000 hp. This conservative estimate of the importance of Maine's water-power is a fair index of the value of the nation's water-resources, by far the larger part of which is yet undeveloped. Great soil-loss is occasioned by tillage methods which permit surface washing. The soil-waste thus started by mere negligence increases until the slopes are gullied, the bottom lands covered with waste, the streams choked, and the navigable rivers filled with bars. So universal and persistent is this drain upon our resources that it is estimated that at least one billion tons of the nation's richest soil is annually carried into the sea by our rivers. The subjects of soil and water-resources cannot be discussed without mention of the conserving influence of the forest. The records of flow of many rivers too plainly show the effect of removing the forest-cover. There is a vital relation between the forest and agriculture, manufacture, and navigation. As the great conservers of other resources the forest deserves the nation's care.

Recent surveys of the nation's coalfields indicate an area for the more accessible coals of 327,000 square miles. This is four times the area of the known coalfields of the rest of the world. In these vast coalfields the nation has available nearly 2000 billion tons of coal mineable under present conditions, or twice the tonnage estimated for the rest of the world. Apparently America's supply is so great as to render immediate alarm unnecessary, but if the present phenomenal rate of increase in consumption is maintained, the supply of easily and cheaply mined coal will be gone before the middle of the next century. The waste of our natural gas supply has been estimated at 1,000,000 cu. ft. daily, or the equivalent of 10,000,000 tons of coal per year. Nor is the record for petroleum much better. In the case of coal there is waste at every stage of mining and consumption. For each ton of merchantable coal brought to the surface at least half a ton is wasted by being left in the ground, or thrown upon the culm pile. Great also is the loss by uneconomical consumption. Less than 10% of the heat units of coal are utilized under the ordinary steam boiler, and in the locomotive the waste is said to be not less than 95%. The record of waste, however, before which every American should stand aghast is that of human life in the coal mines. So far reported, with several States unheard from, 3124 coal miners were killed last year, or an increase of 50% over 1906. It is a matter of some gratification, however, that at last the nation has made some provision for investigations that may prevent or lessen mine disasters.

The iron-ore production last year, reaching 51,000,000 tons, shows an increase of 8% over 1906 and 21% over 1905. Even should the present output continue without further increase, the known reserves will be exhausted within the present century.

The future of metal mining will be governed by the improvement of metallurgical and mining methods and by the available supplies of fuels, water, power, and mining timber, as well as by the discovery of new mining districts. In the determination of the economic value and availability of ore deposits, the fuel and water supply is a more important factor than the character of the ore itself. In a real and large sense the very life of our mining industry depends upon the conservation of all the other natural
resources. Private ownership of natural resources is a form of stewardship, and the duty of man to man and of the present to the future is being recognized as never before. No clearer exposition of this truth has appeared than in the recent opinion of the Supreme Court of Maine, wherein it is set forth that as ownership in land is not the result of productive labor, but is derived solely from the State itself, which was the original owner, and as the land resources are incapable of increase, the State has the right to protect itself against the impoverishment that would follow waste under private ownership. So indicative is this opinion of the national awakening that President Roosevelt devoted a large part of his memorable address on conservation to the Maine decision. A month later the Supreme Court of the United States enunciated a similar principle. These decisions of the highest courts are 'signs of the times' and mark the dawning of an era of conservation. The policy of leaving "to the next generation the national honor unstained and the national resources unexhausted" is the keynote of the new patriotism.

Mercury in ores may be determined accurately by a method set forth by Muller (Bull. Soc. Chim. [4], I., 1169), as follows. When Au and Pb (one or both) are absent, treat an amount of the pulverized ore which is estimated to contain about 1 gm. Hg, with aqua regia in a covered capsule at a gentle heat. After decomposition, evaporate to dryness at about 50°C. Take up with hot water, add about 50 c.c. of a 20% solution of KI and then Na_2CO_3 until it produces no more precipitate. Add a little NaOH to obtain positive alkalinity. Filter, wash with hot water, and extract the insoluble portion with more KI and Na_2CO_3. The extract and washings should come to about 100 c.c. and will contain all the Hg. The test is made on aliquot portions of this, using for 0.1 gm. Hg 20 c.c. of a 20% NaOH solution, and the same amount of formaldehyde, 35%, in stoppered flasks for about 20 hr. at 25°C. Metallic Hg is precipitated, which may be washed by decantation with alcohol, and then N/10 I in excess (known amounts) is added, and the flask set aside in the dark until the Hg has been dissolved. If it has collected in large globules, the cautious application of heat may prove necessary to effect solution. The excess of I is then determined by means of standard Na_2S_2O_3.

Coal production in California during 1907 was the smallest reported in the State since mining began in 1861, according to E. W. Parker of the U. S. Geological Survey. The increased production of petroleum and its use for fuel purposes has had a demoralizing effect on the California coal industry, and except for domestic purposes there is little market for the product. From 77,050 tons in 1903 the coal output decreased to 22,250 tons in 1906; in 1907 the total production was but 13,950 tons, valued at $38,213.

Acetylene lamps have been used instead of candles in a number of mines in the West. It is claimed that the cost of lighting is reduced more than one-half, and that at least six times as much light is obtained.

Rusting of Iron.

Written for the Mining and Scientific Press
By F. H. Mason.

In the Proceedings of the Chemical Society, issued on June 29, 1908, are the conclusions W. A. Tilden has drawn from experiments that he has been conducting over a considerable period on the rusting of iron. They are:

1. Oxygen or air, with liquid water, are alone necessary to produce rusting without the assistance of carbonic acid, failure on the part of other experimenters to produce rusting in iron prepared by treatment with chronic acid being probably due to 'passivity.'

2. Water alone in the absence of oxygen attacks iron slowly, producing a film of what is probably ferrous hydroxide, as it is wholly converted into brown rust on the admission of pure oxygen. In this connection the experiments of Whitney (Journal Amer. Chem. Soc., 1903) repeated and approved by Walker, Cederholm, and Bent (Journal Amer. Chem. Soc., 1907) were confirmed.

3. Iron-rust, even when old and constantly exposed to the weather, always contains ferrous oxide.

4. The process of rusting is due in the first instance to electrolytic action, promoted in all ordinary cases by the existence of carbonic acid in water exposed to air, and by the presence in iron of various compounds of carbon, silicon, phosphorus, and sulphur. That electrolytic action does occur locally in all commercial iron, whether malleable or cast-iron, or steel, immersed in water, is shown by the use of the 'ferroxyle' indicator (phenolphthalein and ferri-cyanide) introduced by Walker and his colleagues. In ordinary rusting the process is also assisted by the depolarizing action of the layer of ferrie oxide or hydroxide formed externally on the rust-spot.'

The subject is eminently interesting to engineers, more particularly in its relation to feed-water for boilers, and in the pumpling of corrosive waters either from mines or in hydro-metallurgical plants. Mr. Tilden has disturbed one theory of long standing, namely, that pure water and air are without action on metallic iron. By his experiments he distinctly proves this not to be the case, but that while carbonic acid greatly accelerates the rusting of iron, rusting may be initiated not only by pure air and water, but by pure water alone. The generally accepted theory of rusting was that while it might be initiated by many accidental atmospheric impurities, it was generally started by carbonic acid. Once the rusting had commenced it was continued by the two hydrated oxides of iron working upon each other and upon the iron on one side, and the air on the other, thus on the side adjoining the iron we find ferrie oxide being reduced by that metal to ferrous oxide, while the latter becomes oxidized to ferrie oxide by the air on the side remote from the iron. Hence, given the condition of a moist atmosphere, the reactions go on continually until the metal is completely oxidized. Mr. Tilden's third conclusion is only what we should expect, for while there is metallic iron there will assuredly be ferrous oxide.
The second part of his fourth conclusion is perhaps the most interesting, namely, that carbides, silicidates, phosphidates, and sulphidates of iron, which exist in a greater or less extent in all forms of iron and steel, are in the presence of pure water, or of pure water and air, capable of promoting electrolytic action, and initiating rust. It would have been even more interesting if Mr. Tilden could have gone farther, and stated whether there was any direct increase of electrolytic action in proportion to the amount of metalloid present in the iron. When the Hub mine in Cape Breton, Canada, was re-opened about 15 years ago, after being closed for 20 years, the iron pipes and tee-rails found, while retaining their original shape, had been entirely converted into a soft material which could be scraped with a pen-knife and cut with a carpenter’s saw. I made a number of analyses of this substance at the time, but unfortunately have retained no copy. I remember, however, that it contained a little over 50% iron, none of which was in the metallic form, but mostly existing as ferrous and ferric oxide, with a little sulphate and sulphide. There was also about 12% graphitic carbon, 3% phosphorus, and considerable silica. The coal in the mine is high in sulphur, and the mine-waters probably contain sulphuric acid, which would form an excellent electrolyte. The carbon must have replaced iron to some extent, and was presumably derived from the coal. The original casting could certainly not have contained as much carbon as found. The fact of the castings having retained their original form is curious. For a long time difficulty was found in pumping at this mine owing to the corrosive action of the water on the pumps. That electrolysis plays a part in the ‘pitting’ of boilers has been known to chemists for a long time, but it has been generally supposed that the boiler-mountings, which are usually made of copper-zinc, or copper-zine-tin alloys, were responsible for the promotion of the electrolysis. Some years ago I conducted a large number of experiments on boiler-feeding waters. The waters were found to ‘cut out’ a set of boiler-tubes within six months, and the matter was placed in my hands for investigation. The source of the water was a lake supplied by a large watershed of uncultivated land. The water in passing through dead and decomposing leaves, and roots of trees, shrubs, and other plants, became highly impregnated with vegetable matter. There was practically no mineral matter, analysis showing less than three parts per million. The oxygen-absorption, as shown by Tidy’s modification of Forchhammer’s test amounted to over six parts per million. In determining the amount of iron attached—it cannot be said to be dissolved—weighed quantities of the best Swedish iron-wire were placed in a large hard-glass flask, in which known quantities of water were evaporated over regular intervals of time. At first spots would appear on the wire, followed by brown fungus-like growths, which were undoubtedly composed of hydrated oxides of iron. The ebullition would ultimately detach these, and others would form in their places. At the end of the experiment the wire was taken out, carefully wiped to remove adhering oxide, rinsed first in distilled water, then in alcohol, dried at 100° C., and weighed. Viewed under the microscope big holes were found where the fungus-like objects had formed. The other parts of the wire were apparently unattacked. When small pieces of brass wire were intertwinned with the iron wire, to imitate boiler mountings, the wire blackened over the whole length before the water boiled, and oxide formed all along it. Microscopic examination showed that while the wire had been attacked along its whole length, the attack had been much more violent in some places and especially at the points where the brass wire was intertwinned. The weighing showed over three times the loss of iron when the brass wire was in contact with the iron wire. A large number of experiments were made before a satisfactory antidote was discovered. Ultimately the addition of bichromate of potash was found to solve the problem. The amount added was small, and the cost of the reagent amounted to only three cents per day per hundred horse-power. It entailed some initial outlay in the way of storage-tanks in which the water and reagent were mixed, but it formed an efficient remedy.

A WATER-WHEEL GOVERNOR AND ITS OPERATION.

Written for the Mining and Scientific Press
By D. Ben Replogle.

Water-wheel governors differ from steam governors in the greater strength and more complex duty required of them. They control water under pressures varying from 3 to 900 lb. per sq. in. They may have duty of 20 up to 30,000 foot-pounds per second; and a 10-hp. wheel may require a stronger governor than a 10,000-hp. wheel, depending upon the volume, pressure, and character of the 'water-shift,' that is, the gates, nozzle, or deflector controlling the stream that enters the wheel. Where the water-shift cuts off the flow instead of deflecting it, changes of pressure result, due to the governor's own action. This and the great strength required, as well as the great range of adjustment incident to varying conditions, have together necessitated a heavy governor of rather complex construction.

In the governor illustrated herewith an attempt has been made to reduce the parts to the simplest form consistent with complete efficiency in performance. The centrifugal balls revolve in a belt-drive wheel and cause the flat discs on the main shaft, by endwise motion, to engage for plus or minus water-shift, according as the speed deviates from the normal. The endwise motion of the shaft is not in excess of $\frac{1}{4}$ in. The shaft is hollow, having a rod extending through its centre and engaging a lever at the end opposite the belt-wheel in such a manner that any swinging of the lever changes the position of the fulcrum of the fly-balls slightly, so as to afford a variation of the speed at which they will 'trip' or cause engagements of the discs. This lever is operated or shifted in its range by means of a horizontal rod actuated by a worm, or cam, moving with the water-shift, and the rod is automatically adjusted in its length by means of a screw, driven by a variable-speed mechanical drive, so as to properly time the engagements as to duration and also to properly vary the tripping-speed of the governor. It will be more readily understood what movements a governor must make by examining the accompanying diagrams. These diagrams apply to the performance of any make of governor, and they attempt to make clear the part of a governor's performance that is complex and obscure to most operators of water-power plants. While the diagrams show the work of three types or grades of machines, the governor illustrated, as well as any high-grade governor, must be adjustable to the work (as indicated in Fig. 2) or to any modifications required of it. On this account, it will be understood, destructive racing could occur on account of failure to properly adjust a high-grade machine. The submitted diagrams are intended to indicate the performance of each of three grades of governors under a 10% instantaneous drop of load. Fig. 2, however, may be illustrative of the performance of a high-grade governor, wrongly adjusted, or adjusted for special compensation. Fig. 1 more especially indicates the performance of a non-compensating governor, that is, one which does not automatically vary its own tripping-speed to meet conditions. Its normal speed remains level at 500 r. p. m.; therefore it will remain in action as long as the deviation of the curve is outside the narrow limits 499-501, which are its plus and minus tripping-points. This performance is nearly always improper in a quick-acting governor, for each engagement is too long, and 'hunting' is the result. If the speed-curve coincided with the normal zone when the water-shift
and load coincide, as at the beginning of the third second, it is evident that no further 'trip' of the governor would result. The power-effect occurring subsequent to water-shift, however, and the speed being dependent on and coincident in time with the power-effect, the speed and load-curves cannot harmonize without compensation.

In Fig. 2 it will be noticed that provision is made for cutting shorter the time of minus trip (and minus shift) due to a drop of 10% of load. The speed reaches the same deviation, 510, as shown in Fig. 1, but the normal zone has been automatically shifted upward by the action taken, and the speed coincides with normal at the end of the third second instead of at the end of the fourth second, as in Fig. 1. The position of the water-shift is such, however, as to cause the speed to continue to fall so that a plus-trip results at the beginning of the fourth second. This causes the water to coincide with the load at the end of the fifth second. This also again shifts the normal zone downward, and thus causes the plus-trip to terminate earlier. This is the compensation which makes the governor satisfied in the sixth second, but the normal speed now remains at 505 r. p. m., and in like manner there will be a varying normal speed, corresponding to all load-variations and water-shift positions. The appliance in a governor producing this characteristic is called a compensator.

It will now be possible to clearly understand the performance indicated in Fig. 3. Here a quicker action on water-shift is permissible because of the extraordinary feature which is introduced, of having the normal-zone shifted rapidly with the speed-curve and automatically returned to its original level at a rate corresponding to the speed-return. This performance allows a plus-trip to occur when the speed is at its highest, and, as shown, this brings the desired tranquilization at level-speed in the fifth second. This shifting of normal-zone and tripping-points then causes the governor to properly select and time its action, even though the speed at the time would, as in case of Fig. 1, cause it to take, or continue in, a contrary action. This is a performance which has been said to savor of human judgment. No man on the water-shift, however, could equal its results in regulation. The appliance in the machine to which this performance is due, I prefer to call a 'tranquilizer.'

Racing, or 'hunting,' as the phenomenon shown in Fig. 1 is usually called, may be due to many other causes than misadjustment of the governor; or, more properly speaking, the defects of the plant outside of the governor may be so extensive that no adjustment of the governor will compensate for them. Among these defects are: lost motion in connections; sticking gates or nozzles; extreme variations of pressure; uneven power-effects at various stages of water-shift; and unbalanced gates or nozzle. Some of these can be met by adjustment of the compensator and tranquilizer, but when the strength of the governor is not adequate for the conditions in hand, and when it has not a fair surplus for emergency, the governor should be discarded as dangerous, and a stronger one substituted. A weak governor or a defective one, failing to act promptly, will consequently overrun when cause accumulates, and the most dangerous hunting or 'runaway' may result.

I have found governors installed which were adjusted sixteen times too quick and others forty times too slow. The former caused a very rapid hunting, the water-shift moving 100% in half a second. The result was an even speed, but an over-tax on the governor. It was corrected by changing a gear in the connections. Where the governor was too slow, a great deviation of speed occurred, but no hunting. A change of governors was necessary. Sensitiveness is not synonymous with quickness. Sensitiveness results from close adjustment of flyball-connections and friction-dises. A narrow normal-zone indicates sensitiveness; a steep water-curve, quickness. Where a safe margin for strength is allowed, and a good type of tranquilizing governor, having a wide range of adjustment, is selected, it will lead to safety and economy in the plant, indispensable under modern demands.

Iron-ore production in the United States during 1907 amounted to 51,720,619 long tons, according to an advance sheet of the Mineral Resources recently issued by the U. S. Geological Survey. This ore had a value of $131,996,147 at the mines. As compared with the production of 1906, the most productive previous year, this was an increase of 8.32% in tonnage and of 31.21% in value. Reports of production in 1907 were received by the Survey from 169 mines, the maximum production of any one mine being 2,900,624 tons, this being the Hull-Rust mine, in Minnesota. Ten mines, all except one being situated in Minnesota, produced over 1,000,000 tons each. The million-ton mine not situated in Minnesota was the Red Mountain, of Alabama, which during 1907 produced 1,370,849 tons, and ranks seventh in the list of producers. During 1907 the United States imported more than 1,200,000 long tons of iron ore. Of this total over half was from Cuba and about a third from Spain. About 116,000 tons came from British North America. Exports during the year amounted to 278,208 long tons, a slight increase over the exports of 1906. The bulk of these exports represent Lake Superior ores shipped directly from American mines to Canadian furnaces.

There are more than 318,000 miles of railroad in the United States.
ASSOCIATION OF MAGNETITE WITH SULPHIDES IN MINERAL DEPOSITS.

Written for the Mining and Scientific Press
By John B. Hastings.

In the Mining and Scientific Press of November 9, 1907, was an article by Geo. J. Baneroff touching on three subjects: the formation of gossan in a moist climate and lately glaciated country; the contemporaneous deposition of magnetite and sulphides; and the solubility and leaching of gold in the oxidized upper portion of a quartz vein. The first and third conditions have been ably discussed in the Transactions of the American Institute of Mining Engineers by T. A. Rickard and other prominent engineers, and by H. V. Winchell, whom Mr. Baneroff quotes. Quite a little, too, has been said about the intimate association of magnetite with various sulphides, but the references have been overshadowed by larger and more valuable information accompanying them on other points. Six years ago I passed through the same stage of wonderment as Mr. Baneroff over the genesis of the blond and dusky minerals, when examining like deposits in Alaska, though already pretty well seasoned to the anomaly by previous residence in British Columbia. Since then I have followed with interest the opinions of the sophisticated on such occurrences. There is no one particular article dealing prominently with the relations between magnetite and sulphides, but the following quotations show partially what a half-dozen of the leading authorities think about it. There are other views on the origin of some of the magnetites of the Eastern States, which are not included, as the conditions are dissimilar to the Western phase.

A. H. Brooks, speaking of the deposits on Kasaan peninsula, Prince of Wales island, Alaska, which are principally magnetite, with chalcopyrite, pyrite, some gold, and a little silver, says (p. 98): "In some of the mine-workings the percentage of magnetite decreases very rapidly below the surface. In these the place of the magnetite is taken by copper and iron pyrite, showing that the occurrence of the former mineral depends upon the alteration of the sulphide minerals near the surface. In certain of the thin sections examined under the microscope, pyrite grains were observed surrounded by secondary magnetite." The ores of the region consist of copper pyrite, with some bornite, closely associated with iron pyrite and magnetite. "The gangue, as far as there is any, includes amphibole, epidote, vesuvianite, and considerable calcite, together with chlorite and jasper," and a little quartz. Present knowledge of these deposits is too meagre to admit of saying much as to their origin, but it suggests analogy with magmatic differentiation. "There has undoubtedly been mineralization subsequent to the cooling of the rock in which they are contained."

I had the opportunity, just after Mr. Brooks finished his studies, of examining some of the most important of the Kasaan peninsula magnetites, though without time for anything more than to obtain direct economic results. The orebodies occur alike in limestone and greenstone, usually in the latter, and in neither rock does it show well-defined fissures. One orebody which was sampled, 200 ft. long and 50 ft. wide, was bounded on four sides, respectively, by white limestone, blue limestone, greenstone, and a light-colored dike (undetermined). All four contacts between the ore and the rocks were clean and well defined and almost perpendicular. The average analysis was 45% iron, 15 silica, 10 sulphur, 5 alumina, 5 magnesia. 2 lime, and in part 25% copper, and 15% oxygen with the magnetite. The chalcopyrite occurs in spots throughout the magnetite, so that when the solid magnetite is broken the copper is seen through the entire mass and not as films along the planes. The other half of the iron body contains more epidote and chlorite. It was thought to be a replacement of blue limestone. The neighboring greenstones were similarly replaced as an extension of the ore-zone. This means a substitution of the ore minerals for the original constituents of the limestone and greenstone, probably from solutions ascending along favorable lines—joints, bedding-planes, contacts, and fracture-planes, and then gradually spreading. It also means an able-bodied carrier, undoubtedly water.

W. Lindgren, describing the deposits of Clifton-Morenci, Arizona, says: "Magnetite, pyrite, chalcopyrite, and zinc-blende accompany in various proportions the contact metamorphic minerals, and are intergrown with them in such a way that the contact metamorphic origin of these ores appears beyond doubt," resulting from "water and metallic substances which were originally contained in the magma of the porphyry . . . released by decreasing pressure. . . . We may thus speak of these deposits as contemporaneous with the cooling and solidification of the porphyry." They are more or less irregular in form, influenced by stratification-planes and dikes acting as boundaries. The fissure veins seem to have been formed a short time after the consolidation of the porphyry. (p. 21) "In the lower levels the veins consist of pyrite, chalcopyrite, and zinc-blende, magnetite being conspicuously absent.

This is perhaps slightly modified on page 98, where he says: "Fissure veins in limestone are accompanied by quartz, magnetite, and amphibole, as metamorphic minerals," and on page 28, "... metamorphism resulted in metasomatic development of garnet, epidote, diopside, and other silicates, accompanied by pyrite, magnetite, chalcopyrite, and zinc-blende. The sulphides are not later introductions, but contemporaneous with the other contact minerals. The contact zone has received very substantial additions of oxides of iron, silica, sulphur, copper, and zinc, enough to form good-sized deposits of pure magnetite and low-grade deposits of chalcopyrite and zinc-blende." Again (p. 102), "Magnetite . . . in great quantities appears in the contact metamorphic limestones and dolomite limestones, where it is associated with garnet, amphibole, pyroxene, and sulphides. In structure it is usually granular, but when disseminated in limestone it also occurs in crys-
talline form. It is found wherever contact-meta-
morphic alteration has taken place; especially large
masses, economically important as flux for smelting
purposes, occur in the Manganese Blue and Arizona
Central mines, as well as on the hill slope southwest
of the latter mine. A large body also occurs in the
gap where the road to Eagle Creek descends into the
Gold Gulch valley. To a minor degree it is also
formed as a metasomatic product in limestone, rarely
in porphyry, along the walls of the fissure veins
which cross these rocks. It alters to limonite, and
sometimes also to hematite, as is well shown in the
iron stopes of the Manganese Blue mine. . . . Meta-
somatic processes are those by which, through chemi-
ical reactions, and mainly by aid of water, one min-
eral is changed into another. . . . Rocks are meta-
somatic if any or all of the constituent minerals have
undergone partial or entire metasomatic changes.
. . . In contact metamorphism . . . the prin-
cipal minerals formed are garnet, epidote, wollas-
tonite, pyroxene, amphibole, magnetite, and pyrite
in the limestone, and amphibole, epidote, feldspars,
biotite, andalusite, and quartz in clay shales. . . .
These changes . . . are usually attributed to the
combined influence of heat and magmatic water
pressing outward from the cooling intrusive rock.
. . . Hydrothermal metamorphism is a form of
alteration in most cases confined to the close vicinity
of fissures. Much of the ore may be produced in
this manner by replacement of country rock. The
minerals most commonly formed in this district are
pyrite, sericite, calcite, and quartz, but it will be
shown that magnetite, pyroxene, amphibole, and epidi-
ete may also be formed by these agencies . . . "
In descriptions of individual localities, summary and
discussion, etc., not included in this article, he says:
"Magnetite . . . oxidizes at the surface to hematite,
which is usually loose and cellular, and black from
accompanying peroxide of manganese. Limonite is
the final product. Near fissures and in orebodies in
altered limestone the oxidation of magnetite may
proceed to a depth of 200 ft. or more." S. F. Emmons,6
speaking of the ores near Green-
wood, British Columbia, says: "The association of
magnetic oxide of iron, in considerable amount and
of contemporaneous formation, with sulphides of
iron and copper (more particularly the latter), is a
peculiar occurrence I had never had occasion to ob-
serve until last summer." The type is similar to
Lindgren's contact deposits, except for the apparent
absence of eruptives in the immediate vicinity.
W. H. Weed7 quotes R. W. Brock on the same
mines—and I take it that Brock had no doubt about
the simultaneous deposition of the magnetite and
sulphides: "Brock distinguishes two types, a pyritic,
characterized by pyrrhotite, with chalcopyrite and
iron pyrites, and a magnetite type, with magnetoite
and copper pyrites. Though segregated in places,
the chalcopyrite is remarkably evenly distributed
through the deposits. Rarely do magnetite and
pyrrhotite occur in the same deposit. . . . Brock
considers the orebodies to be composite veins formed
by mineralizing solutions traversing the country rock,
principally along fissures or zones of fissures in which
they deposit the economic minerals, and from which
they replace with their mineral contents, particle by
particle, sometimes completely, the original material
of the country rock."
A. C. Spencer,8 describing the Treadwell mine,
Alaska, says: "Magnetite occurs only in the form of
minute grains outside the veins. Part of it appears
to have been an original constituent of the diorite,
built much of it was deposited secondarily along with
the pyrite, perfect cubes of which it sometimes sur-
rounds." These veins are infiltrated materials mak-
ing up one-fifth of the mass of the altered diorite
constituting the Treadwell ore deposit.
W. Lindgren9 also says that, "Magnetite also oc-
curs with epidote and pyrite, as probably segregat-
massie leached from the surrounding rock, in
the tunnel of the North Star placer mine . . . " at
Grass Valley, California.
J. F. Kemp10 describes a Mexican deposit, saying:
"The ores are probably caused by an intrusion of
diorite porphyry, in Cretaceous(?) fine-grained blus-
lish limestone. Contact effects have changed the lime-
stone to white marble, garnet, and other lime sili-
cates. . . . Magnetite is a contact-mineral locally
developed in irregular masses which are of very con-
siderable size. On the borders they are intermingled
with garnet and diopside, and throughout the mag-
etite are abundant veinlets of chalcopyrite and py-
rite. . . . The magnetite must have been intro-
duced in the same way as have the silica and alumina
which have developed the silicates. . . . In the
cooling of the eruptive there must have been a stage
when the emissions were of necessity gaseous, and a
later stage when they were liquids. . . . In his
study of the Clifton district, Mr. Lindgren has at-
thributed the garnets and other silicates to the stage
of gaseous emissions, particularly of water-gas
accompanied by silica and iron. This is quite rea-
sensible, and it may be that at San José the garnet-
zones, the magnetite, and the copper ores were
formed at this time. From the evidence in hand,
however, there seems no reason to eliminate heated
waters as also possible agents. . . . The bodies of
magnetite were doubtless formed by direct replace-
ment of the limestone with the iron oxides, and seem
to indicate a local richness in iron for the emissions
from the eruptive where they are found . . . There
is alight, if any, reason to regard them as other than
purely contact-products. . . . The introduction of
the sulphides seems to have been, in largest part, one
of the later phases of the contact-metamorphism,
and to have followed the production of the silicates
at least in part. We infer this from the relations
described under the sulphides that, besides forming
inclusions in the silicates, they mold around the ga-
rents, and follow crevices in the magnetite."

EDITORIAL.

A T A RECEPTION in San Francisco on Tuesday night Mr. E. H. Harriman revealed how the denunciatory and legal prosecution which have followed him and many of his enterprises in recent years, have rankled in his bosom. "We do not want to be regarded as a machine, but we would be treated as human," were his words. But there is the crucial point. Had Mr. Harriman recognized that the railroads are national and not individual arteries of commerce; had he taken to heart the full significance of the law constituting railroads 'common carriers,' with right to invoke in their behalf the high governmental prerogative of eminent domain; had he realized that so-called private 'ownership' in railroads can, in the nature of the case, be nothing more than a trusteeship; then he would have made the management of the railroads under his control as mechanical as the discipline that gives him efficient service from his employees, and as free from the bias and unjust discrimination of an unmechanical, humanly wilful administration, as he possibly could. The nearer Mr. Harriman, as railway magnate, acts the part of an emotional machine, dispensing special favor to none, the more will he win respect and consideration for himself as man. Mr. Harriman is one of the most plausible of speakers, but his appeal for sympathy was, after all, but a poorly veiled thrust at his strenuous antagonist in the White House.

Increasing Activity in Gold Dredging.

F ROM one of the odes of Horace—forbearing to quote the Latin—we translate, "Nothing is too hard for mortals to do." It seemed a forlorn hope to subdue a 'geologic frost,' and win the gold locked in an icy grip that had held on for ages. There were despairing ones who cried the thing impossible, but it has been done, and the ease of the solution, as explained by Mr. T. A. Rickard in an article on 'Dredging in the Yukon,' appearing in this issue, reminds one anew that the most troublesome problems are generally worked out by taking advantage of natural phenomena. Man must perforce use Nature to overcome Nature.

Dredging of the frozen gravels in Alaska is now an accomplished fact within limits of economical operation. This opens up a vast new field. Exploration of the North may be said to have only fairly begun. The arctic wilderness cannot be investigated in detail far ahead of the slowly advancing outposts of civilization. It offers difficulties of its own which hold back even the most adventurous spirits, as drought and famine held them back for decades from the great American desert. But the conquest of the North is taking place with immense rapidity.
and the extent of auriferous gravel beds offers enormous opportunities for dredging enterprises.

The search for gravel deposits has become perhaps the most notable feature of recent activity in the mining world. A stream of engineers has been pouring into Colombia during the last twelve months investigating the riches of the Cauca valley. Mr. F. Lynwood Garrison, in a letter from Antioquia, appearing in our special correspondence this week, points out the highway leading to this important goldfield, which he will later describe for us as a result of his investigations. The quest is active throughout South America. Parties are in the field re-examining the deposits in eastern Peru, and others in northern Argentina. Mr. F. J. H. Merrill describes in another column a group of interesting placers in northern Sonora. Though he calls them ‘dry placers,’ the term is only relative. Water is available in most cases at no great distance, and if the problem of clarifying enough water from the pool to admit of efficient operation of the gold-saving devices be solved, there is no good reason why ordinary dredging should not be extended to such fields also. The experience at Oroville has shown that it requires but a small percentage of argillaceous matter in gravel to hold water in a pool. A dredge has climbed out of the Feather river through the old tailing of the hydraulic mines to a height of thirty feet without difficulty. The limiting conditions for successful dredging are constantly becoming less in the face of conquering human ingenuity.

Protection of Mine Investors.

THE Mining and Metallurgical Society of America announces that the subject for discussion at the September meeting will be the protection of mine investors. This is placing the emphasis where it will lead to a clearer conception of the responsibility of the engineer. It tends to a distinction between engineer and client, between technologist and layman. It recognizes that the investor is a layman, and consideration of the engineer as his counsellor follows in natural sequence. The existence of mining engineering as a profession rests in drawing such a distinction, and in the creation of restrictions founded upon a conception of a body of trained men on the one side, and of a public requiring its services on the other. The laws relating to architects may perhaps be taken as a starting point, indicative of practical methods for reaching a solution of the problem. The line of demarcation between the trained architect and the man who has grown up in the business as a builder and contractor, has been hazily drawn, just as the line separating the mining engineer from the practitioner who has gained his knowledge solely in the field, remains indistinct. The matter is settled in the case of architects by examination before duly constituted commissions. An examination may not necessarily determine ability, but it is the only practicable way of winnowing the wheat from the chaff. But when this is done, it will be found impracticable to shut out unlicensed practitioners from doing actual engineering, just as the State laws are forced to recognize the right of builders to design and erect structures. But the building trade does not come into touch with the stock market, while mining operations do. Therein seems to lie an opportunity for restrictive measures which will at once differentiate the profession as a recognized body of technical advisors, from the investing public. The endorsement of a licensed engineer upon a mining project constituting the basis of a stock company, as a prerequisite for the issuance of stock, would produce a destructive drought, drying up the streams that now turn the mills of unscrupulous promoters. This would tend to bring both mining corporations and mining engineers to a sounder basis of business procedure. The local engineer needs to become recognized as useful and available, in the same way as a local civil engineer, architect, or physician is recognized and consulted. The mining engineer of the future must necessarily be less of a nomad than formerly. Thus will he gain both in influence and in the substantial development of a dependable practice. His has too long been the romantic profession. It will benefit by sacrifice of the glamor.

Ethics of Technical Writing.

In the beginning let us establish clearly that ethics is a broad term, generously inclusive of those things necessary to be done for the welfare of society. Ethics in its far Grecian origin meant ‘character,’ the thing that was wholesome and virile and fruitful of good to the race. It consequently includes all that is morally right, and much more that is merely right because expedient. Thus it expresses the duty of responsibility to society, and shifts as the needs of advancing civilization shift. Two of our correspondents have raised questions of ethical relationships between the technical writer and the world he addresses, which are worthy of closer investigation. Technical writing is writing about the way to do things, about the practical art which promotes human welfare, in both a static and dynamic sense. It is part of the eternal obligation of mankind to assume the function of teacher. The man who does not provide his children an education is compelled by law to let the State educate them. He may not set back the race by bringing up illiterates. Whether moral law has anything to say upon this subject or not, society has and always did have a great deal to say upon it, and has been ceremonious in its observance of the rites of education from the days of earliest barbarism. Education has been ever bound up with what man has been pleased to look upon as sacred mysteries. The most practical technical school has never yet succeeded in shaking off this spell and reducing itself to the status of a mere workshop. So he who writes, except the mere purveyor of daily news, is supposed to have a message. If he has not, why should he write? When he takes up his pen he has become the schoolmaster, in which he displays a creditable sentiment, whether or not his contribution advance the cause of education. He has at least shown himself possessed of a more commendable spirit than actuates him who accumulates knowledge and locks it up. In the Middle Ages a man possessed of special scientific
knowledge was in some peril of being deemed a wizard and of having to pay the penalty of death for it. Later the technologist, such as he was, became revered and honored, and he and his co-workers were recognized as possessing 'secrets' too valuable for bestowed upon the world at large. That was the early equivalent of the modern patent. Today the 'secrets' are pretty well out, and young men are instructed in them as principles essential to their equipment for doing the serious work of the age. Moreover the technologist who has not discovered or worked out something which was not understood before, and who has not told his fellows about it, has come to be looked upon in the modern world with suspicion. He is liable to indictment as an ingrate or as an incompetent. Every man must be a schoolmaster. It is part of his sacred duty to the race.

It is evident that the ethics in the case have changed materially within the last six or seven centuries. The duty of a man to set forth what he has learned is a high one. It was for a time recognized as such. But within the last few years an unfortunate reaction has set in, which gives to a discussion of the ethics of technical writing a timely value. On the one hand the cheapness with which periodicals may now be printed, because of improved machinery, wood-pulp paper, and photo-engraving, has called into existence a host of weeklies and monthlies representing not only every art, but even the petty divisions of the arts, until the bewildering multitude is as ocean, in which if a man throw his contribution it is liable to be swallowed up and lost. Perhaps worst of all among these 'organs' of special knowledge are many of the publications sustained by departments of universities. Keen editorial selection is not applied in such cases as it is where a paper is compelled to fight for support and win its way by virtue of excellence. The tendency has been to that sort of shallow verbose scientific dissertation which is called sciolistic. There has been a deluge of sciolism. The authority of the printed page has been weakened in consequence. Perhaps this is no evil in itself. Instead of acquiring dignity by the mere fact of being published, as once was the case, a printed statement must now stand chiefly on its own merits. Type no longer gives to a dictum patent royal. Thus sciolism is subject to the laws of Nature, and like every growth secretes its own poison.

Another circumstance tending toward disregard for the obligation to impart the knowledge gained from experience is rooted in one of the most serious defects of the times. The worship of money has always been strong since the day when the devil invented it, but it remained for this mechanial age to erect the pursuit of money into a cult, and to require of every man that he pursue it eternally. It had never before been required of man that he devote his quota of working hours to economic endeavor only, and his spare time to pure play. It had never before been true that if a man chose to relax by doing some useful thing, and to describe the fruits of his work for the benefit of other men, he should be accused of not being busy, and he suspected of the unpardonable sin of financial failure. As there is today much pretense of knowledge, so is there a vast deal of foolish pretense of being busier than the facts justify. This will doubtless work its own cure ultimately, as sciolism is doing. And in the return to reason, each will discover the necessity of being a teacher and of helping forward the world by adding his mite of knowledge, in requital of his advantage in starting with the legacy of the accumulated knowledge of ages past. This is the first duty under that department of ethics which relates to technical writing. After that follow considerations of responsibility as a writer.

Probably no man can write from unmixed motives to do good to others. The doing of good work will benefit him in a material way, and he cannot remain unconscious of the fact. It is a pleasure to one's vanity to have done a thing well, and it is mere hypocrisy to pretend the contrary. A man who takes the attitude of a scientific altruist is either a knave, a prig, or in very truth a hero. For most men a fair sprinkling of self-interest and vanity will not do material harm, if modified by honest scrutiny of the facts presented to the world. This is nothing else than the scientific spirit, which has exalted truth under the influence of the modern inductive method of research. That it should be necessary for 'Escrutador' to challenge the writings of technical men on this account indicates how far the commercialism of the period has been drawing the technologist away from his scientific moorings. In part this is due to disregard for the truth, in part to over-confidence in the scientific value of a great deal of the training given in technical schools, and finally a large cause is to be found in positive ignorance of the principles of evidence. Few men are thoroughly efficient in the examination of scientific evidence. It requires a particularly broad training, and the cultivation of the logical faculty to an extreme degree. It is the same principle that lawyers apply in the court-room, which reveals, in the embarrassments of cross-examination, how seldom any man, with the best intentions in the world, can state "the truth, the whole truth, and nothing but the truth." Yet must we bear witness to the things we have seen and believe. The judge has a penalty for contempt if a witness would refrain: the technologist must produce his testimony from a sense of obligation to his fellow men.

A NOTABLE MEETING of the Canadian Mining Institute is in progress, involving an excursion from ocean to ocean. Delegates from many foreign technical societies are in attendance. In celebration of the event the Canadian Mining Journal has prepared a beautiful brochure and map illustrating the mineral resources of the Dominion. With astute suggestion to the future prospector a bold red line is traced across the map, along which runs the legend, "Country north of this line virtually unexplored except along some of the principal rivers." It is surprising to find this line dipping north of Lake Superior to well below latitude 60°, within a degree and a half of the International boundary.
Personal.

C. M. Rolfe is in New Zealand.
FRANK M. Estes is at El Oro, Mexico.
A. H. Bradford is at Golden, Colorado.
J. F. Kemp, of New York, is in Mexico.
R. H. Campbell is at Teller City, Alaska.
J. M. Evans is at Parral, Chihuahua, Mexico.

John G. Morgan was at Nome on August 25.

Walter Harvey Weed, of New York, is in Arizona.

Whitman Symmes has gone to Mokelumne Hill, California.

Robert T. Hill is making a tour of the Western mining districts.

Horace J. Stevens, of Houghton, Michigan, was in Butte last week.

FRANK G. Manley, of Hot Springs, Alaska, is on his way to Boston.

A. E. Drucker is installing a cyanide plant at Kuk San Dong, Korea.

J. H. Hamil is operating on Esther creek, in the Fairbanks district.

C. M. Hampshaw is returning to New York from the Rampart district, Alaska.

Mark B. Keen is inspecting properties at Grass Valley for San Francisco clients.

H. Foster Bain has returned to Urbana, Illinois, after a trip to the Pacific Coast.

FRANCIS A. THOMAS has recently been in Nevada, and now is in British Columbia.

WILLIAM C. Magee will be at Britannia Beach, British Columbia, for several months.

James P. Kinball is in central Idaho, inspecting dredging ground for Eastern clients.

M. W. Lovemade, of San Francisco, is making a ditch survey in the Hot Springs district of Alaska.

A. V. Thomas is superintendent for Frank G. Manley at Glean, in the Hot Springs district, Alaska.

Mark R. Lane is at the Rio Plata mine, Chihuahua, where a new cyanide plant is being installed.

J. P. Rowe, geologist at the University of Montana, is making a study of the Coeur d’Alene district.

W. D. Pearce, of Chihuahua, is now in Nevada making examination of mining properties for Eastern clients.

Edgar B. Van Osdel has been appointed professor of chemistry at McMinnville College, McMinnville, Oregon.

E. H. MacDonald, of Butte, Montana, was engaged in geological work in the region of Lake Pend d’Oreille, Idaho, last week.

A. H. Brooks, chief of the Alaska division of the U. S. Geological Survey, is making his annual tour and is now at Fairbanks.

Harry C. Klaus and Harry L. Wolfenberg, of Berkeley, California, are in Sonora, in charge of explorations for a California syndicate.

Lee Fraser, of Saginaw, Michigan, has accepted a position as engineer for the Agua Caliente Mines, Inc., at San Mateo, Costa Rica, Central America.

Arthur S. Langley, assayer at the smelter of the Britannia Copper Syndicate, Ltd., at Croton, has been transferred to the mine at Britannia Beach, British Columbia.

Arthur C. Terrell, for the past two years professor of mining and metallurgy at the University of Oregon, has been appointed professor of metallurgy at the University of Idaho.

MINING AND SCIENTIFIC PRESS

September 12, 1908.
General Mining News.

ARIZONA.
COCHISE COUNTY.

(Special Correspondence).—A strike of rich ore is reported to have been made at the property of the Bisbee-Donor Development Co., 30 miles northwest of Tombstone. The discovery is an outcropping vein near the office of the Company, and the miners have been walking over it for the past year. Two miners are at work breaking ore for shipment, and more will be started soon.—Ore carrying free gold has recently been found by W. H. Smith on his claim at Paradise, near the Willie Rose. The property is not a new one, but was worked 30 or 35 years ago, and the recent strike was made in an old inclined shaft.—The adit at the Virtue mine, at Portal, is in 252 ft., and it is the expectation of the management that the vein will be struck within the next 25 ft. The work on the group of claims owned by John A. Duncan, near Paradise, is being centred on the Sunflower and Comanche Chief claims. A quantity of track was recently moved from the Mayflower to the Sunflower adit. J. G. Sweeney has sold his lease on the Columbia to Bernouy & Wright, who, it is stated, will commence shipments at once.

Paradise, September 5.

GILA COUNTY.

The shaft of the recently re-opened Stonewall mine, at McMullen, has reached a depth of 150 ft., and a cross-cut started at the 90-ft. level has been driven 65 ft. to a connection with the old workings. The shaft will be sunk to the 300-ft. level before any exploring is started. V. Y. Smith is the superintendent.

MARICOPA COUNTY.

The famous Vulture mine, near Wickenburg, has been sold to Philadelphia and Baltimore capitalists for $500,000. The new owners are expected in Wickenburg at an early date, and it is believed they will at once resume operations. D. J. Curry, of Wickenburg, represented the former owners.

MOHAVE COUNTY.

A new strike has been made at the 600-ft. level of the McCracken mine. Four and a half feet of ore was uncovered in a cross-cut, which samples 103 per ton. Small streaks of the vein assay several thousand dollars per ton. The mine is 75 miles southwest of Kingman.—The Tom Reed Co., recently made a clean-up after a 15-day run at its 10-stamp mill, near Kingman, the bullion amounting to nearly $40,000.—J. W. Thorn, of Car-bg, is preparing to resume work on his Horse-bone mine, near that place, and will sink his shaft 100 ft. deeper.

YAVAPAI COUNTY.

The management of the Monica mine, 13 miles north of Kirkland, is planning a 40-stamp mill to take the place of the existing 20-stamp mill. Sixty-five men are employed in the mine, and the mill is treating 60 tons per day. The process is crushing in cyanide solution and subsequent cyanidation.—The Big Stick Co. is at present working 22 men in the mine. A 20-stamp mill is being erected and the management expects to have the plant in operation by the first of the year. The ore of the Big Stick averages between $7 and $12 per ton gold and comes from a vein which is five to seven feet wide.

CALIFORNIA.

NEVADA COUNTY.

(Special Correspondence).—James Williams and associates have located three claims above Bowman’s Dam, and expect to work their holdings on a large scale during the fall.—H. G. A. Brunner has announced that funds will be forthcoming for the liquidation of the indebtedness of the Conlan G. M. Co., and that work will soon be resumed at the mine.—The station for the electric pump at the 1300-ft. point in the Prescott Hill shaft of the Sultana mines has been completed and the machinery will be immediately put in. The pump has a capacity of 600 gal. per minute.—Operations have been discontinued at the Dolly Madison and the machinery is being hauled away.—The Lecompton mine has been unwatered to the sump below the 500-ft. level, and active work will soon commence. A large compressor has been ordered for the property.—The Eastern company operating the Norambuiga has placed an order for a large compressor.—The Liberty and Virginie claims have been purchased by A. Becker, and a force of men put to work.—Joseph Welsbien and Mark B. Kerr, of San Francisco, are inspecting the Gold Flat, Federal Loan, and other properties in the Nevada City district. Work will be resumed at the Gold Flat in the near future, according to the present plans of Mr. Welsbien, the principal owner.—The working force at the Idaho-Maryland is being steadily increased. The work of re-timbering the shaft is proceeding steadily.

Grass Valley, September 7.

SAN BERNARDINO COUNTY.

Gold Valley is the name of a new mining camp in the Gold Belt mining district, about 25 miles southwest of Hart and 14 miles southeast of Cima, on the east slope of the Providence range. Last winter a number of Hart people made several locations in that vicinity, and everyone who has visited the district declares that the showing there is good. Quite a rush is now on at the new gold camp, and it is said everything within miles around has been located. A township has been laid out and over 50 tents have been put up. At a depth of 100 ft. Warfield & Neumeyer have opened a 16-in. streak of free-milling ore which gave $100 returns on two tons of ore worked through an atraria. A two-stamp Nisen mill has been ordered.

SHASTA COUNTY.

Another contract for 100 ft. of tunneling has been let by the directors of the Grand Central Mining Co., for work on their recently acquired mining property in Harrison Gulch. The moving spirits in the enterprise are C. C. Corbile and his brother, of Redding.—The Bank of Shasta County has commenced foreclosure proceedings against the Phoenix Security Co., inquiring properties in the Butte Hill district, as well as the Mount Shasta gold mine, near Shasta.—The Dorlesa mine, on Union creek at the head of Coffee creek, is at present under lease to M. L. Melville, who has been doing development work.

SISKIYOU COUNTY.

Fred Sears and D. J. McFall, of Nevada City, have taken a bond on the 16 to 1 lode claim, at Alleghany, and expect to organize a company to develop it.—The Bonanza King mine, near Alleghany, the controlling interest in which is owned by Flynn Bros., has been bonded for three years to a San Francisco company. According to the terms of the bond, work must be started immediately. The consideration is said to be $10,000.—A stamp-mill is to be erected at the Omega placer mine, at Forest. Some of the richer gravel is cemented to such an extent that a mill is necessary to break it up.—Five additional stamp-mills and a tramway will be added to the equipment at the Papoose mine, in Jim Crow canyon. Adam Keffer, of Downville, will have charge of the mill.

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence).—Work is to be resumed at an early date upon the holdings of the St. Paul M. & M. Co., on Green Lake Mtn. The adit is to be driven steadily forward for the intersecting of the St. Paul vein, which is supposed to lie about 400 ft. distant. The St. Paul is an extension of the Colorado Central, lying to the west. The adit has been advanced for 1400 ft. and previous to the suspension of work last fall a promising vein had been intersected. Mont Tong, of Georgetown, is in charge of the work on the Montgomery-Ward adit, which is being driven steadily forward in a satisfactory manner. Since the hanging-wall of the Pay Rock Extension vein was reached, driving has been under way and there is showing in the heading a streak of high-grade silver-lead ore that is from 4 to 6 in. wide, and
The examination of the Minersville claims, tunnel-site at Breece, has been completed, and as soon as plans are formulated a consolidation of the Everett and Minersville holdings will be perfected. W. H. Maxton is in charge of development.—The Seven-Thirty M. & M. Co. has just been organized, with W. A. Hoos, of Silver Firme, serving as managing director. This company will complete the work of putting through the raise to drain the Seven-Thirty tunnel; and it is to be resumed, within a few days. The Pelletier mill, with a daily capacity of 250 tons, has also been secured and the machinery is running day and night. People of the district interested in mining are anxiously awaiting the draining of the Seven-Thirty mine workings, as a large block of virgin territory will be opened for exploration. A number of lessees have already made applications for drill privileges, many of which will be granted soon as the preliminary work has been completed.—Skews & Clair, leasing on the third level of the Smugzler, have shot into a streak of ore (that is 18 in. wide. A shipment was sent out last week and settlement was made at the rate of 137 oz. silver and 20% lead. The ore was found 140 ft. from the shaft. On the fourth level Franchini, on a 15-in. area, is mining on nodules of medium grade ore that mills an average of $30 per ton in silver and lead. Announcement has been made that on October 1 work will be put under way in the sinking of the shaft another 100 ft. This work will prove of great importance, as the ore-shoots of Brown Mtn. are known to extend to a great depth, as has been ascertained from development of the Terrible mine. The Terrible vein runs parallel with the Smugzler, lying a short distance away. Work has again been resumed upon the Tom Payne property, on Democmt Mtn. These holdings have recently been purchased by E. K. Coss and a company is now in the course of organization. The adit is in 600 ft., and from surveys the heading should cut under the shaft workings within 15 ft. Ore of a high grade was mined from the original workings.—E. C. Grubbs is developing the Teddy group of claims on Columbia Mtn. The adit is being driven ahead at the rate of 3 ft. per day, while a streak of mineralized quartz is exposed that is 10 in. wide.—James Oldfield, owning a group of 17 claims and a tunnel-site on Red Mtn., in the Daily district, has started work and promises to continue development through the winter months. Mr. Oldfield is interested in a number of other claim-holders who reside in Tennessee. The Butler property is making a good showing, and occasional shipments of ore are being sent out. No effort is to be made for a heavy production, pending the completion of the 50-ton concentrating mill which is in course of construction. E. M. Mosecript, of Idaho Springs, is manager.

GILPIN COUNTY.

A carload of machinery, comprising a compressor and complete equipment of drills, was recently received at Black Hawk for the Buckley mine, in the Eureka district. W. Murphy and associates have recently purchased the property and will begin work at once.—Colorado and Eastern people have become interested in a lease and bond on the Gladstone and Rhodes claims, in the Idarado district, owned by John Brohl of Central City. The main work is to be done on the Gladstone shaft, which is down a depth of 220 ft., and which is equipped with a good plant of machinery and a shaft building. The lessees have already started to uncover the shaft, and as soon as possible will commence the work of sinking it at least 100 ft. L. D. Wray has been engaged in charge of operations and the working force will be increased as soon as possible.—The Lone Star group of 12 claims and a tunnel site on the south side of South Boulder creek, in the Wisconsin district, has been purchased by James A. McCracken, of Toland, from the estate of the late Milo T. Straight, of Denver. The new owner will begin work at once, and expects to continue all winter.—Denver people are unwatering the winzes below the adit of the Copper Jim property, in Wisconsin district, for the purpose of examination. The winze is 40 ft. deep and some high-grade silver and copper ores have been taken from it in a fair-sized streak.

LAKE COUNTY.

The old Forepauch shaft, at Leadville, is being worked through the Sliver. A number of Flinsh miners have secured a lease on it and are producing a regular tonnage of good ore. The shaft-house on the Forpauch, which was destroyed by fire last fall, has not been re-built, but there is a possibility that it will be before long.—A new engine and hoist are being put in at the No. 7 shaft of the Matchless, preparatory to exploring the large ore body to which such high-grade gold discoveries were made when Senator Tabor owned the mine. Shipments are being made regularly from the No. 5 shaft to the Arkansas Valley smelter.—Charles Aichers, who has been working on the Eclipse property, on Breece hill, during the past few months, has closed up his work there and is now transferring his plant of machinery to the Quincy claim, in South Mosquito. As soon as the machinery is placed the work will start sinking.

TELLER COUNTY.

The Strong Gold Mining Co. is to start within a short time the erection of a new ore-house at its property on Battle Mtn., near Cripple Creek.—McCauffery & West, of Pueblo, who have a lease on a group of claims on the northwest slope of Tendefoot hill, expect to start a shaft for exploring several large veins which outcrop. The lease is a favorable one, being graded royalties.—Morris Bros., who are operating on the Morning Star, on Bull hill, are installing a hoist to take the place of the windlass now in use. Notwithstanding the poor equipment in use in the past, shipments have been made at the rate of three cars per week, from which returns are as high as $200 per week. It is reported that the Wishbone mill, on the extreme northern slope of Tendefoot hill, will be entirely overhauled and roasted added. It is probable that a spur from the Colorado Springs, Cripple Creek District railway will also be built. It is the intention of the owners, who are St. Louis capitalists, to treat custom ores, as the ore in the company mine did not prove payable.—The H. G. Burgmann has secured a lease on the Half Moon, of the Maton Gold Mining Co., a Stratton Estate corporation, and will soon place the property on the shipping list.—The Blue Flag mill, on the east slope of Raven hill, resumed operations last week, after a close-down of some time. The plant has been thoroughly overhauled and repaired, and is now in good shape to handle the output of the mine. No attempt is being made to operate the plant at its full capacity, and only a portion of the full force was put to work. The mill is treating ore from the mine, having an average value of about $4.50 per ton.—The entire plant of the British American Mining Co., Ltd., at its property near Victor, was destroyed by fire in the night of August 31. The majority of the loss is covered by insurance. The shaft itself was not injured, but the buildings of the shafthouse were destroyed. The fire is believed to have been of incendiary origin.—William Matney has secured a lease on the Maggie No. 2, at Cripple Creek, and will start active operations immediately. The lease runs for a term of 18 months, with graded royalties. The Maggie adjoins the Pointer property on the south, on which a good strike was reported to have been made.

IDAHO.

OWFFEE COUNTY.

A larger air-compressor has been ordered for the Potosi, which will be of sufficient power to run 12 or 14 drifts, and with the one now in use will enable the work in the mine to be pushed much more rapidly than at present.

IDAHO COUNTY.

It is announced that the Graham-Ross Co., recently reorganized by the bondholders, will begin work on the Ana-
of a new boiler, the construction of a 4506-ft. flume, from the mine to the south fork of Big creek, and the erection of a saw-mill. Ten men are engaged on the property at present and all are being occupied with driving on the vein. The Clearwater Gold Mining Co. is expending between $5000 and $6000 per month in operating the property. The Company’s claims are in the St. Joe country and take in over two miles of the creek bed.—The long flume from Moon gulch to the property of the Wisconsin company has been completed and the machinery for the compressor ordered. This mine has been under development for many years and several shipments have been made. The company now has over $4000 worth of ore in the smelter.

The Company’s claims are in the St. Joe country and take in over two miles of the creek bed.—The long flume from Moon gulch to the property of the Wisconsin company has been completed and the machinery for the compressor ordered. This mine has been under development for many years and several shipments have been made. The company now has over $4000 worth of ore in the smelter.

Perhaps no camp in the district is more active at present than the Spring City field, south of Joplin. Two new shafts are being sunk at the Aiholin mine upon good new prospects. Both galena and zinc-bullion ore are found on the road and expected to arrive daily. All the buildings and the hunk-house have been completed, and the flume is ready to connect up. Two assessments for $15,000 each will be made later.

WALLACE, September 5.

MISSOURI.

JASPER COUNTY.

(Special Correspondence).—The ore prices for the week were a little higher than usual. The Blackberry mine, at Joplin, sold its ore for $39.50 per ton. Silicate advanced from $18 to $22 per ton and lead is normal at $61. The largest producer in the district was the Underwriter’s Land Co., at Webb City, with 550,500 lb. zinc and 192,820 lb. lead. Its total tonnage was the American Zine, with 170,680 lb. zinc and 170,860 lb. lead, while the third was the Kansas City-Bradford, with 482,020 lb. zinc and 19,570 lb. lead. The total value of the output for the entire district was $355,855. Perhaps no camp in the district is more active at present than the Spring City field, south of Joplin. Two new shafts are being sunk at the Aiholin mine upon good new prospects. Both galena and zinc-bullion ore are found on the road and expected to arrive daily. All the buildings and the hunk-house have been completed, and the flume is ready to connect up. Two assessments for $15,000 each will be made later.

The Plata Mining Co. has begun the development of a ten-acre tract on the McCowan land.—New machinery has been added to the Argosy plant, at Spring City, and the mill has been overhauled, increasing the capacity of the plant. The new Delville mill is still the best of the few in the district without a tailing elevator. This is unnecessary because the mill is situated high on a hill and the tailing is carried down the hill-side direct from the jigs. The shaft of the Delta is down 165 ft., though the other shafts in the camp penetrate the same orebody at 100 ft., the variation in the depth of the shaft being due to the elevation of the mill. About 40 tons per week are being produced at this mine. The Alpha mine, one of the steady producers of the district and an old producer, has resumed operation, having been closed down many months owing to the high waters of last spring and the low ore prices of the summer. The ground has been well worked, and there remains much uncertain country. A 150-ton mill is on the lease. Drilling operations are in a new portion of the lease have been completed in two lots, and a new shaft connected with the mill by a tramway.—Two of the oldest mines in the district are being operated. The Beeville mine, south of Carthage, is being operated by C. F. McElroy, who is taking out a large quantity of lead carbonate. Over 30,000 lb. have been taken out in the past three weeks.

The Mooney mine, south of Joplin, is being pumped by the Shelly company to remove water again for smelting. The mine was operated by the Confederates during the war, when the lead was used for bullets. A lead smelter is known to have been operated on that land many years before the war.—Preparations are being made by a number of companies to erect milling plants this fall on their leases.
A large plant will be erected by Budd Robinson, on the Clarycomb land west of Chitwood, where a good mine is being developed. A number of drill-holes blocked out the ore deposit and a shaft has been sunk. A 35-ft. face of ore was penetrated extending to 155 ft. Five hundred feet of drifts have been run and 200 tons of ore have been piled on top.—A 200-ton mill on the Criterion lease at Davidson, is planned. The last year has been given over to development of the ground. Two shafts are in ore at 200 ft. and three working drifts have been opened up. The ore is sheet-ground and carries a good percentage of galena.—The Sunset mine, south of Duenweg, will have a new mill. The shaft is down 132 ft., from which point a drift is being run. Budd & Robinson & Co. have completed a 150-ton plant south of Duenweg, near Wolfe City, the plant operating on a continuation of the orebody found in Sucker Flats. This land is in a badly-cut condition though there is much mineralized territory still.—There will be four new mills on the 40-acre tract of the Cosgrove land, at Duenweg, one 200-ton plant having just been completed and the others planned for the immediate future. A 10-acre subplot has been taken by the United States Co. and Bru- baker Bros. have taken the remaining 30 acres. Several drill-holes were sunk on the land, not one proving a blank. The orebody occurs at 197 to 256 ft.—A new plant of 200 tons capacity has been recently completed by A. L. Shepard, of Chicago, on the Center Creek Mining Co.'s land. Development work is carried on below the 106-ft. level. The adjoining ore plots have been leased by Shepard, and the old Bessley mill has been overhauled and greatly enlarged. The ore is developed from 125 to 130 ft. and is a continuation of the famous Kansas City-Bradford mine in the same vicinity.—Among the rich strikes recently reported in the district is the find in the Try More mine, at Leadville Hollow, near Joplin. The deposit was found above 106 ft. and is rich in galena and zinc-blende. This strike has greatly stimulated prospect work in the vicinity, drill-holes being sunk on both the Leonard and Granby lands adjoining. The Leonard shaft has almost reached the ore, while the shaft on the Granby struck a limestone bar and was abandoned. A second has been started.—One of the best recent strikes was made in the Lucky May, southwest of Joplin. Ore was found at 107 ft. and the drill-record shows 69 ft. of good ore. Drifts in several directions show a 35-ft. face of ore. A 150-ton mill has been contracted for. The mine is in the same vicinity as the Morning Hour, Big Three, and Pumpkin Head, all famous producers, and the new property bids fair to rival these.—Moonshine Hill, east of Joplin, is to be developed by B. F. Wurzel and associates. The water level here is low since the shut-off is about 50 ft. below Missouri L. & Z. Co.'s pumps. A drift is being driven at present to connect the two shafts, 240 ft. apart, and though the work was done for the purpose of connecting only, a good strike of ore was made.—While sinking a deep well in Alba, for the city water supply, an ore strike was made at 510 ft. The ore is rich zinc-blende. A careful record of the strata will be kept, which will prove valuable to the prospector and geologist, as the well will probably be sunk to 1600 ft. and will be the deepest well in the northern part of the district.

Joplin, September 5.

MONTANA.

JEFFERSON COUNTY.

(Special Correspondence.)—The Boston & Corbin mine was acquired by a Boston company, headed by M. L. Am- ster, in February, 1907, since which time the property has been developed under the management of H. E. Emerson, formerly on the staff of the Amsterdam at Butte. Locally it is known as the Bertha mine, and is situated a mile from Corbin station. There are three veins, carrying cop- per and silver, two of which have a northeast trend through the granite country. The three are within a zone 250 ft. wide. The principal development is on one of the veins, consisting of two adits, 1500 and 1000 ft. long, respectively, the latter being 375 ft. below the former. A 300-ft. shaft has been sunk from the lower adit, giving a depth of 675 ft. on the vein. One of the other veins has been opened by a cross-cut from the shaft. Total development aggregates 5000 ft., of which 2500 ft. has been accomplished within the last year. The ore is said to average 4% copper and 6 oz. silver. It is stated that a concentrating plant will be erected next spring.—The Black Jack mine, in the same district, is being developed by a small force. It belongs to Couch & Duan, of Great Falls.—The old Alta mine, a former producer of silver and lead, which has been idle for 12 years, is reported sold to parties who will start it again. The Alta veins, also in the granite, strike at right angles to the Boston-Corbin veins. The Alta was well developed and well equipped with milling and mining machinery. The Ballard mine, belonging to Ballard Bros., of Jefferson, is situated at the head of Precly Pear valley, near Mt. Baldy. A vein of free-milling gold ore has been opened, some of the high-grade of which has been hauled to the railroad and shipped, the returns amounting to about $50,000. A mill will be built.

Corbin, September 2.

NEVADA.

EMERALD COUNTY.

Rawhide was almost completely destroyed by fire, which started on the morning of September 4. The cause of the fire was the explosion of a gasoline stove in the basement of a drug store. The fight to save the town was greatly handicapped by want of adequate water supply. The business part of the camp is completely wiped out, but no injury was done to the hoisting plants of the mines. Trainloads of supplies were rushed in from Reno, Tonopah, Goldfield, and surrounding camps, and none suffered from hunger or exposure. The work of re-building has started and the min- ers are all at work. L. W. Hill, of the Boston-Corbin Co., has leased and bonded the seven claims constituting the Zion group, be- longing to the Zio Con. Mining Co., lying three-fourths of a mile northwest of the Great Bend, in the Diamondfiel district, and has also leased and bonded the Jefferson mining claim, on Masonic Mtn., 12 miles north of Bodie, Mono county, California. The leases and bonds have 18 months to run, and it is the intention of the lessees to begin active operation upon the properties at once.—The shaft on the Fairview-Cherokee lease on the Atlanta is to be sunk 200 ft. from its present depth of 545 ft. Heavier machinery will also be put in.—A movement is on to construct a street railway at Goldfield, the line to have Diamondfiel as one of the termini. The route partly determined upon is by way of the Consolidated mill, Columbia, and the prin- cipal mines of the district, also traversing the business and residence sections of the city. T. F. Manning, George Wing- field, and L. T. Merwin will make application for a fran- chise at the next meeting of the board of county commis- sioners. The proposed company has already been finan- ced to the extent of $125,000.—The mines of Goldfield pro- duced during the week ending September 5 a total of 2705 tons, estimated at $172,240. During the same period the Tonopah mines produced 6570 tons, of an esti- mated value of $725,500.

HUMBOLDT COUNTY.

The 10-stamp mill of the Seven Troubles Kindergarten Mining Co. treated 183 tons of ore during August, and pro- duced a bar of bullion weighing 1216 oz. and valued at

In the middle of the United States, the Department of the Interior has been inspecting the mining operations of several companies. One of these companies is the Goldfield Blue Bell Mining Co., which has recently acquired the Stakes property at Berlin, consisting of 25 patented claims, including the Berlin, Shamrock, Downesville, and Richmond groups. The Berlin mine is well equipped with a hoist, machine shop, compressor, lighting plant, and a

20-stamp mill. S. T. Pearson, who is manager, has been putting the plant in shape and was preparing to go to work this week. F. W. Blair, who is superintendent of the Aurora, at Sprucadale, has gone to Milwaukee to purchase a hoist, and possibly a reduction plant, for immediate use on that property. —The Wild Bill Mining Co., at Manhattan, has purchased a five-stamp mill and it will be put into place at once on the Company's ground in the northern mineral belt. —The Mayflower, at Rybohite, will resume operations at once, and will probably build a small mill for experimental purposes. Sidney Additon has recently succeeded Robert Smith as superintendent.

OKLAHOMA.

OCTAVIA COUNTY.
(Special Correspondence.)—All northeastern Oklahoma is being prospected for ore and indications are favorable for a splendid continuation of the Joplin field into the new State. Several leases near Nacissa have yielded good strikes of zinc-blende. On the farm of W. H. Sutton, at Grove, both galena and zinc-blende have been found. In the Spavinaw hills, 40 miles south of Miami, a company of Muskego men have begun operations and are finding good ore. Other points in this State report good strikes. —Pipes are being laid from Miami to the mining camp to supply the mines with oil which will be used exclusively as fuel. Although oil has been used in emergencies in other parts of the district, this is the first time that an attempt will be made to use it as the principal fuel. —A shaft is being sunk at the Miami Bunny mine southwest of the present shaft. This will not soon enter the producing list. —The King Jack, another new mine, began operation this week, and, while not running steadily, made a good record. Last week four tons of zinc-blende and three tons of galena were shipped.

Miami, September 8.

WASHINGTON.

FERRY COUNTY.
(Special Correspondence.) —The wagon road for hauling ore from the Manila mine to the Keller & Indiana Co. smelter is nearly completed. Upon completion of the road the Company will immediately employ a large force in two shifts, blocking out and breaking down ore. A contract for hauling the ore has been let to Martin & White, of Republic, who have purchased eight large ore-wagons and 32 head of horses and expect to haul from 30 to 40 tons per day. The Company expects to have 1000 tons of ore on hand and to blow in the smelter about October 1.

Republic, September 4.

STEVENS COUNTY.

(Special Correspondence.) —A gasoline engine, blower, and additional pipe have been delivered at the Trojan mine, and fresh supplies have been sent in for the immediate reopening of operations. —At the Daisy mine, near Addy, an adit is being pushed rapidly forward. At about 500 ft. from the portal a vein of ore assaying well in gold, silver, and lead has been struck. It is 4 ft. wide. —The Bonanza mine, near Bossberg, which has been under operation from time to time, with varying success and for several months before the last financial panic was operated extensively, is again under development. It is expected to ship about 300 tons in the next few months. —The Company is reported to have a five-year contract for the disposal of its ore. —The old buildings at the United Copper mine, near Chewelah, have been torn down and a new engine-room and blacksmith shop have been completed. The buildings and mine have been wired and are now lighted with electricity. A new orebody, 5 ft. wide, parallel to the vein which has been long under development, has been struck on the 357 ft. level. The character of the ore is different from that hitherto found in the mine, and it carries about 8% copper, and also assays higher in silver than any ever before found in the mine. The two veins are separated by a few feet of shale. The new discovery has been followed with a drift, in over 60 ft. The ore from it will be handled separately, and the two veins have a total width of from 10 to 12 ft. —The new concentrator of the Spokane Lead Mines Co. ran only ten days after completion before it was closed down. Liens have been filed by 28 workmen, and, those, together with the claims of the Union Iron Works of San Francisco and other large creditors, amount to about $30,000. From the mill-run 7500 lb. of galena-concentrate, assaying 76% lead, was cleaned up. Mismanagement is charged. An extraordinary strike of ore was reported to have been made in the Mina claim, owned by the Company, two days before the mill was shut down, which is said to have been unknown to the Company. Stockholders are asking for an explanation.

Metaline, September 2.

MEXICO.

The Tequari mine, three miles northeast of Sahuaripa, Sonora, has been taken over by the Mesa Rica Gold Mining Co., a Milwaukee company organized by J. J. Smith, A. F. Tanner is the manager. The property has a 10-stamp mill and plans to build a tramway and install the machinery. The company's offices are in the Calumet building, Chicago. —The Mineral Development Co., of Guanajuato, is making arrangements for funds to continue work on the Nueva Luz mine, in the La Luz district. The shaft is now down 1200 ft. H. H. Miller is the manager. —The Mexican Standard Mining Co. has been organized at Denver, Colo., to operate the Candiaia mine, at Parral. J. S. Jones is the president and N. H. Partridge the manager. The mine has been owned by these men for some time. —The Oaxaca Smelting Co. has been reorganized and the early opening of the plant is assured. —It is reported that the El Tigre mine, Sonora, has been bonded to the Phelps Dodge Co. of New York and Arizona. The price is said to be $8,000,000. A railroad from Zacate to the mine is contemplated and the Chihuahua and Durango Co. at San Julian, Chih., is operating 15 stamps, and with the installation of the Krupp mill will have a capacity of 50 tons daily. Gerald V. Hopkins is the manager. —The Sonora Copper Co., operating at Cobre Grande, Son., via Noria, has developed extensive orebodies and is planning to erect a smelter. A. M. Conard is the manager and Bert Cunningham superintendent. The property has been under development for about a year. The Natividad Mines & Reduction Co., San Sebastian, Jal., is erecting a 200-ton cyanide plant. The Company is largely owned in Berkeley, Cal. —The San Francisco del Oro mines, an English corporation, will build a railroad from the end of the Company's tramway to the Mexican Central's line between Parral and Santa Barbara.
MINING

Special Correspondence.

LONDON.

Operations of Williams, Harvey & Co. in Cornwall. — Scurvy in the Arts. — Rival Flotation Processes. — Conditions at Broken Hill.

In writing of Cornish tin-smelting works recently, I mentioned the fact that the old firm of Williams, Harvey & Co. have several years ago sold their old works to that firm, and that it might now be called the leading smelting firm in Cornwall. This progress is due to the management of Mr. Gilbert Pearce, and to the money and the knowledge of smelting of Dr. Richard Pearce, late of Colorado. Another evidence of the prosperity of this concern is the expressed intention of starting a branch works to the north of England, by the midsummer of this year. It is intended to treat at the new works some of the imported ores that come from Bolivia and elsewhere. These ores are at present shipped to Liverpool, and transshipped thence to Cornwall for treatment. Another advantage in having a works at Liverpool is that much of the tin produced is used by the bronze-makers in the north of England. In addition, tin will cost less in Cornwall. Cornish smelters do not tell the whole world, what they actually do. They do not encourage the visits of strangers or journalists, especially journalists representing American papers. That leads me to take this opportunity of reminding American readers in general and the owners and metallurgists of great American smelting works in particular, that their pleas against secrecy in the arts are all very well for those who have an Anandara or a Queen in their back yards, but they do not appeal to English custom-smelters, with whom superior technical knowledge and experience is the sole stock in trade. Consequently it is not at all surprising that Cornish tin smelters should keep their business to themselves. Those tin smelters in Cornwall are quiet in their doings altogether. They are not in the habit of making public their intentions and methods, and they omit no fumes to advertise their presence.

I have on several occasions referred to the litigation between the rival flotation processes, one owned by the Minerals Separation, Ltd., and the other by the Ore Concentration Co., Ltd. The first process is the invention of Messrs. Ballois, Sollman & Picard, and is a development of the duplex process of the latter which is the Elmore vacuum process. I am personally much more familiar with the latter than the former, for I have had opportunities of studying its action at Tywarnhaile and Dolcoath. The Minerals Separation process is not in operation in this country, and is being developed at Broken Hill. Though not familiar with its workings, I have J. H. Curie’s assurance that he has made experiments on the Broken Hill plant fully bear out the claims of the inventors. The old original Cattermole plant was erected at the Central mine, Broken Hill, belonging to the Sulphide Corporation, and, as I said in an article some time ago, did not give very good results. It is now closed down. The next plant, on an improved model, was erected by the Sulphide Corporation at the Central mine to treat the residues coming direct from the jigs. During the year ended June 30 last, this plant treated 170,000 tons, and produced 64,000 tons of zinc concentrate. The plant does not yet give as good results as the Company counts on obtaining eventually, and gradual alterations are still being made. The next plant erected was the joint venture of the Minerals Separation, Ltd., and the Sulphide Corporation, and its object was to treat the residues coming from the jigs and “dust” slime purchased by the Minerals Separation, Ltd., from the Block 10 Co. This plant treated 5772 tons of Block 10 slime, but is now closed owing to the unsuitable terms available for the sale of the concentrate. A fourth plant has been erected by Minerals Separation, Ltd., conjointly with other parties, to treat the tailing-dumps on the Central mine, which have been purchased from the Sulphide Corporation. This was completed in November 1907, and from that date to June 30 last, it treated about 100,000 tons of tailing and produced 36,000 tons of concentrate assaying 45% zinc, 15% lead, and 15%/ oz. silver per ton. The recovery is 83% zinc, 66 lead, and 73 of the silver. This plant, if worked continuously, will handle 5000 tons per week, though it was designed to treat only 2000 tons. The cost of the process, including trammel, re-grinding, flotation, and handling residues and concentrate is given at 76¢ per ton. For one thing, it was tried with a plant that had previously been in operation on another process, and furthermore the working of the process was not in the hands of the inventors’ representatives. I have already mentioned that the slump in metals has had a disastrous effect on most of the silver-lead mines of Broken Hill. The report of the Broken Hill Proprietary for the half-year ended May 31 last completes the tale. The Company has certainly made a profit, but it amounts to only $27,776, as compared with $138,900 for the preceding six months, and $205,000 a year ago. In 1902 and 1903 also the profits were very low owing to the fall in metals, and only small dividends were paid. In the old “carbonate-days” princely profits were made. Later, with higher silver, dividends were smaller, then monthly. Afterwards, when the zinc question came in, dividends were paid quarterly. I think this is the first time that the half-yearly results have not been sufficient to pay a dividend. The output for the last half year was 36,140 tons of lead and 2,829,799 oz. silver. The average prices obtained were $12 11s. per ton for the lead, and 2s. 3½d. for the silver. In the half-yearly statement, the directors make two interesting announcements. One relates to a zinc experimental distilling plant has been such a success that £100,000 is to be spent in erecting a plant which will produce 8000 tons of spelter per annum. The other is in connection with the exploration in depth. Operations at the 1300-ft. level have proved the body to be 26 ft. wide. At the 1400-ft. level the vein is just as strong, varying from 6 ft. to 44 ft. wide, and running 30% lead, 16% zinc, and 14 oz. silver.

TORONTO, CANADA

Great activity in mining has prevailed during the last few weeks as regards actual development, production, and the operations on the stock market. The continuance week after week of heavy shipments from the leading Cobalt mines has resulted in an active demand for dividend-paying stocks and a steady upward tendency in prices. This, at first confined to a few of the larger and more firmly established enterprises, has lately affected the lower-priced stocks, and has considerably raised the level all round. La Ronge Consolidated and other developments, amounting to 2273 tons since January 1, being far in excess of those of any other mine except the O’Brien, which is a good second with 2213 tons. The Princess, included in the La Rose consolidation, is yielding rich ore from a 4-in. vein at the 70-ft. level. A new vein was struck in driving on this vein last week, which assays 4000 oz. silver per ton. At the Temiskaming a new find is reported at the bottom of the new shaft which is being sunk away from the ore deposits to serve as the main shaft. At 70 ft. a blind vein of calcite, carrying niccolite and native silver, was found, which is stated to be of great width. The Crown Reserve is proving very rich. On the open-cut, now down 63 ft., from which ore valued at $350,000 has already been taken, a block of ore which will yield over $100,000 is ready to break down. A wings is down 29 ft. from the
is a good showing of gold ores, the leading display being that of the Laurentian mine, in Manitou Lake district, which shows 50 oz. of almost pure gold nuggets, valued at $4000. There is also a full representation of the iron, nickel, oil, and cement industries. The Governments of New Brunswick, Nova Scotia, and Alberta present extensive and valuable collections, that of Alberta comprising numerous samples of coal, which extends extensively in that province.

The summer excursion of the Canadian Mining Institute, which has been traveling in Nova Scotia and Quebec since August 24, visiting the plants of the Dominion Iron & Steel Co., Dominion Coal Co., Nova Scotia Steel & Coal Co., and other concerns, came to an end on September 3, and, after a trip to Niagara Falls, left for Cobalt and other points in northern Ontario. The excursionists, numbering in all about 50, include many noted British and German mining and metallurgical experts, and are in charge of W. G. Miller, Provincial Geologist and President of the Institute. The scientists from abroad expressed great surprise at the extent of the coal and iron industries of Nova Scotia and the thorough equipment of the plants.

MEXICO.

Oro-Settlement in Mexico. — Conditions in Western Chihuahua. — Power-Plant on Guerrero River. — New Mill of Dolores Mining Co.—Installing Plant for Rio de Plata Co.—Improvements Contemplated at Sabuyacan Mine.

The recent excellent showings made by the Dolores, the Republica, the Rio de Plata, and other properties in western Chihuahua are attracting mining men and capital to that region, where it is known that a number of promising but as yet undeveloped properties are situated. There is great difficulty in buying them from the present holders in anything like reasonable figures, as they will not take into consideration the expenses that must be incurred to successfully operate properties in the wild parts of western Chihuahua. Though the completion of the Kansas City, Mexico & Orient railroad will give improved and cheaper transportation facilities, there are many mining companies operating at distant points in Chihuahua, as well as all through Mexico, who have to pay from the mine to get their ores to the railroad station. Added to this are many other expenses not known in the United States, which must be taken into account by the mine operator in Mexico. This point is perhaps best illustrated by actual shipments that have come under my notice, from which may be taken one of a lot of concentrate when silver was 56c. per oz. The concentrate contained 15.5 oz. silver, and 3.15% lead, so that the full metal-content paid for in the smelter-liquidation was $612. From this were deducted for railroad freight and smelter charges (the concentrate being high in zinc and sulphur) $32.76; the Federal tax on the silver amounted to $22.71 (deducted by the smelter as a convenience to the shipper); so there was left an apparent net smelter-return of $558 per ton. But in Mexico there must go with every ton of ore a regular bill of sale which must be stamped by the seller at the rate of one-half of one per cent, or five cents for each $10, making on the above ore $2.84 per ton. Then there is a State tax (in Chihuahua 1.2% on concentrate, and 11% on ore), to the receipt for which must be added Federal stamps amounting to 20% of the State tax, or, for concentrate being considered, $5.65 State tax, plus $1.12 in Federal stamps, a total of $6.80 per ton to pay the State taxes. And to get the concentrate to the railroad the shipper had to pay $65 per ton for burro transportation. The total charges then against the $612 were $118.64, of which the State and Federal Governments got $32.35, or 52.9%. From the remaining $491.36 had to still be paid five cents of milling, plus for transportation $2.84, plus then that the investor hesitates, even over a remarkably rich property, unless it can be obtained at reasonable figures? Stamps on pay-rolls, books, and various other papers will easily bring the 5.29% contribution to State.

Map Showing Position of Cobalt and New Districts in Ontario.

O’Brien is represented by a nugget of 850 lb., and a slab of native silver 4 ft. long, carrying about 90% silver, and also by the finished product in the form of six silver bricks from the Deloro smelter. The manner in which the by-products are saved is also shown by samples of the speiss produced after extraction of the silver, and of the cobalt and nickel oxides extracted from the speiss. The Coningas Reduction Co., which treats the output of the Coningas mine at its smelter at Thorold, Ontario, has also been successful in this respect. It is represented by a silver bar 998.4 fine, and specimens of pure commercial cobalt oxide and white arsenic extracted from the ore, indicating the satisfactory solution of the smelter problem, which so long engaged the attention of Cobalt smelters. The La Rose has an instructive exhibit of several blocks of ore, showing the mode of occurrence of silver in association with calcite, niccolite, chloroanite, and other minerals. There
and Federal Governments up to 6% of the gross value of the output of the mines, and from this charge there is no escape, no matter what the method of treatment. In fact smelting makes it slightly less by reason of the deduction for smelting charges before calculating stamps on the bill of sale. But the high transportation charges, which only the highest-grade ore and concentrate can stand, has forced the operators to put in mills, and in western Chihuahua the ore is usually of a character that permits of concentration followed by cyanidation. This has taken place for a long time at the plant of the Dolores Mining Co., in the district of Guerrero, Chihuahua. The August output was 46 tons of bullion, valued at $146,000, and about 20 tons of concentrate assaying about 600 oz. silver and 15 oz. gold per ton. This Company has almost completed its dam on one of the tributaries of the Guerrero river, and will soon have its hydro-electric plant installed to run by electricity at both mine and mill for the greater part of the year. The Republica Mining Co., in the Rayon district, holds about 400 acres including 8000 ft. of river, and when I arrived in Colombia I was further informed that a 300-ft. dam has been opened up on the 300-ft. level. The Company has completed and put in operation its 10-stamp mill, including Wilfey tables, tube-mills, and Butters filters. The mill will be enlarged to 40 stamps as soon as development work permits, but up to the present time the shipments have been about 50 tons per month of 1000-oz. silver concentrate, with no gold. If properly informed, the Company has made no shipment of bullion. The Rio de Plata Mining Co., in the Guazapares district, has had its 30 stamps in operation for almost a year, producing 30 to 40 tons monthly of 2000-oz. silver concentrate, and since the first of July has been operating by water-power. This Company is now busy installing tube-mill and a 10-stamp mill, and a No. 10-stamp mill for the treatment of tailing. The Batopilas company has for several years kept its freight bill down by shipping bullion instead of ore and concentrate; the Wat- terson Gold Mining Co. placed itself this spring in a position to do the same; and the Sahuayacán, which is preparing to resume operation, will probably soon do likewise. It is almost imperative that they do so.

**ANTIQUA, COLOMBIA.**

The Road to the Caucal Goldfields. — Scenes on the Way. — Steam-shovel Work at Panama. — Widening the Culebra Cut. — Chief Difficulties in Canal Construction. — Port of Barranquilla. — Entrance to the Cauca Valley.

I sailed from New York July 4, 1908, on the Hamburg-American steamer *Prinz Joachim*. As I looked over the passenger list and learned something of the nature of the cargo, it appeared to me a disappointing and mortifying fact that a ship carrying 80% American passengers and 95 to 100% American freight should sail under a foreign flag, and when I arrived in Colombia I was further informed to find that nearly all of the trade with the United States is in the hands of German houses. Similar conditions exist in other South American countries. The German in these countries is essentially a trader. He does little to develop the country in which he settles. He marries and amalgamates with the people for purposes of trade, claiming nevertheless his German allegiance for obvious reasons in times of trouble, and he prospers above all others.

The first call was at the port of Kingston, Jamaica, now arising with painful slowness from the ruin of the recent earthquake. To my surprise I found the place dirty and uninteresting, manifesting all the tendencies of petty shiftlessness in spite of the usually excellent British colonial institutions. On the way down the coast I was left to themselves I believe these people would rapidly drift to disorder, and be little better than Hayti and Santo Domingo. From Jamaica it is a run of 20 to 24 hours to Colón on the Isthmus. I had expected to spend three days there, but was forced to rest content with one. A short stop at Culebra and over-night at Panamá was the best we could do. To anyone familiar with steam-shovel work in the Lake Superior iron mines and at Bingham, Utah, the magnitude of the Culebra cut did not seem remarkable, although as to efficiency I doubt if it has ever been exceeded. Having but a few hours to go over the work, I was unable to study the rocks, but I judged them to be mostly crumby tufts and conglomerates. The Culebra hill is decomposed to a great depth, hence the wedge-work is easy. The slopes are bench'd, the cars and shovel being on parallel tracks upon each bench. As fast as a train is loaded, another train of 'empties' takes its place, and the work proceeds with marvelous dispatch. The ground is broken by drilling a series of holes on the line of the bench with light (4-lb.) chur-drills operated by compressed air, the little cut being made as a reservoir for the machine, and utilizing a compressor plant originally intended for ordinary air-drills. The large holes made by these chur-drills enable big charges of explosive to be used, and enhance the efficiency of the work with a saving of labor and perhaps no greater expenditure of explosive. It is generally conceded that the Culebra cut has been but 12 ft. to 15 ft. in length of time necessary for its completion determines approximately the time necessary for the completion of the work. To my mind the difficulties of this cut are relatively small as compared with those incident to the construction of the locks and dams. With the highly efficient system now in operation at Culebra, it will, I believe, be able to move from the locks, however, as soon as the rolling mill was originally expected long before the locks are completed. It seems certain that the slope of this cut will have to be much flatter than was expected. As the soft decomposed volcanic material is exposed to the air and rain it sloughs off, and rolling down it would choke up the water-way and be a constant menace to passing ships. Hence the present slopes must be operated in such a way as to be objectionable and in the end would be more expensive. It would seem, therefore, that the probabilities are, that nearly double the amount of material will have to be eventually moved at Culebra than was originally expected. The sanitation of the Canal Zone has justly received praise and is a triumph of what science, system, and unhampered authority can do. The most extravagant claims of the most observers, and in cases of fever as under the French regime, there are now scarcely dozens. On the whole, I believe the Panamá Canal will be an undertaking of which the Nation may well be proud. A day and a half after leaving Colón brought me to Sabanilla, the port of Barranquilla. A little 'one-horse dinky' railway of English construction and management connects this port, 60 miles away, and 17 miles apart. Sabanilla is a mere roadstead and shallow at that. The railway company has constructed a long slimy pier out to deep water. Should this decrepit structure collapse, Sabanilla would cease to be a port, and this great territory of Colombia would lose its most important trade centre. Barranquilla is quite a large town, built upon the west side of the delta of the Magdalena, and lying on sand it is healthy. It has one good hotel, very fair shops, and the people are courteous and obliging. This town could be easily made a good port and harbor, were the bars at the mouth of the Magdalena removed and docks furnished for the shipping. This, however, would involve an expenditure of sums of money quite beyond the purse of the town of Barranquilla, and possibly of the Government of Colombia itself. This would, however, connect the sea-borne commerce directly with the great system of inland navigation offered by the Magdalena river and its tributaries. The case is like that of the Mississippi and New Orleans. I found a powerful gasoline launch which had been sent down from New York, awaiting me at Bar- ranquilla. It had been built by the Bureau of Construction, was the property of a private citizen, and was put up to the tender mercies of some Colombian engineers, its engine and electrical appurtenances were in hopeless confusion. It took an experienced man four or five days to put the boat in order. From this follows the moral, not to trust your machinery to South Americans unless you are on hand yourself. The
Magdalena river system is navigated by shallow-draft boats, precisely like those on the Mississippi river, having high-pressure non-condensing engines, using wood for fuel. The passenger accommodations are fair, and the freight rates appear moderate, considering the distances traversed, the sparsity of population, and the difficulties of navigation.

Two days on a river-steamer bring the traveler to Magdalen, a town of some importance a few miles below the Bona Cauca, or mouth of the Cauca river. From here I went up the Cauca river in a gasoline launch, towing a large canoe with provisions, gasoline, and other supplies, the distance from Magdalen to Caceres, where I now write, being about 150 miles. Where the Nechi river joins the Cauca the auriferous gravels, which have made Antioquia notable, begin to be found.

**BUTTE, MONTANA.**

All of the mines of the Boston & Montana Co. have resumed operations after a shut-down of three months. The Leonard, West Colusa, and East Colusa mines were operated during most of the time, and the ore shipped to the Washoe smelter at Anaconda, but the two other big mines of the Company, the Pennsylvania and the Mountain View, were closed. These produce about 2,500 tons of ore per day. The concentrator at the Great Falls smelter was started on September 1, and the blast-furnaces will be started during the coming week. The Mountain View mine opened a week ago, and the Pennsylvania last Monday, about 900 men being added to the Company's payroll. No more ore is being shipped to the Washoe by the Company. On the first day of shipments to the Great Falls smelter the Great Northern railway hauled 2,000 tons, and it is expected that the railway and the concentrator will be able to handle the mining operations. The Leonard mines from 3,500 to 4,000 tons per day, the average being about 3,500 tons. It is likely that the September copper production of the Butte district will reach, or exceed, 30,000,000 lb. of copper.

The Anaconda Co. has completed the enlargement of the shaft of the Belmont mine, which is now of the standard 3-section type. When it is re-timbered new boilers and machinery will be installed, and the machinery of the Corra mine, owned by the Butte Coalition Co., may be used. The Belmont shaft is connected with the workings of the Anaconda mine at the 1,500-ft. level.

Ben B. Thayer, assistant to H. H. Rogers, president of the Amalgamated Copper Co., is in Butte, engaged in making his semi-annual inspection of the Amalgamated mines, smelters, and other properties. Mr. Thayer is very optimistic about the future of the copper industry, and the business of the country in general. “Improvement is slow but steady,” he said. “Copper is selling today at 13% to 14c., and everyone looks for a steadier improvement from now on, but I think it may be somewhat slow until after election. There is no doubt in the world that the supply of copper is liberal, and the machinery and railway supplies means that the railroads themselves are experiencing improving business. Bumper crops are expected and the railroads will have to put in use many of the idle cars. The demand for copper is bound to increase as general business increases, and I look for much better prices very soon. There is nothing to talk about a surplus copper supply. I do not think that supply and demand will ever be out of line. In the hands of the producers there has been very much less than is now, and it is a well-known fact that consumers are working from hand to mouth, and have not yet come into the market for their normal supplies.”

The Tuolumne Copper Co. has given a contract to the Erie City Iron Works for six additional 150-hp. boilers, which will give the Company a total capacity of 900-hp. for its hoisting plant, air-compressor, and pumping machinery. The boilers will be of special construction, to stand 150 lb. working pressure. They will require a building 80 ft. long. They are also to be constructed with a gravity system for disposing of ashes and refuse under the boilers. The Tuolumne Co. reports continued improvement in the orebody which is being developed on the 1,000-ft. level. A vein 26 ft. wide has been cut and driving is being done on it. It is said to contain 4 ft. of rich ore, and it is the intention of the Company to open it on the 900 and 600-ft. levels. The orebody is not, however, continuous, for the vein was cut and carried forward and found to contain little of value there. The Company feels no confidence of the permanency of the ore deposit and extent of it, that it ordered a new Nordberg first-motion hoisting-engine some time ago. Two large ore-bias were recently completed, each having 300 tons capacity.

A large quantity of lumber and machinery for the British-Butte Mining Co. has been delivered on the Company's placer-ground west of Butte and the work of erecting the $80,000 dredging-plant has begun. The pit in which the dredge will be first operated is 150 ft. square and 12 ft. deep. Only 7 ft. of water will be required to float the dredge, and three large dams have already been completed. They have a capacity of 10,000,000 gal. of water, which will be held in reserve for dredging operations. A five-year contract has been entered into between the British-Butte & Power Co. for electric power. The dredge has a capacity of 2,500 cu. yd. of ground per day, and 300 hp. will be required for its operation. The Company owns, or rather claims, about 1,000 acres of ground, but the Government is contesting the Company's right to all of it on the ground that it is not valuable for placer mining, though the Company's manager claims it will yield several hundred cu. yd. of gold per day.

The ground was taken up originally by the promoters of the British-Butte as quartz ground, and the Company was floated in London as a copper proposition, notwithstanding that there is a gravel deposit more than 1,000 ft. deep, bock-rock not having been found anywhere, though a shaft 700 ft. deep has been sunk through it.

The Butte & Superior Co. have started work on the Blackrock group of claims lying north of the North Butte mines, has become involved in litigation with John McAlpine, a millionaire lumberman of Duluth, and one of the Company's stockholders, which may result in inimitable and serious controversy. McAlpine is being sued by the Company for $300,000 on stock subscription and subscription and he refuses to pay on the ground of fraud and misrepresentation. He makes and is supported by the statements of Mr. H. C. Caceres, who was in a position to have knowledge of the business at the time the stock subscription was opened. He had two attorneys in Butte looking up the affairs of the Company and the value of its properties. There was much talk of an unfavorable character about the organization of the Company and its floatation by John H. Simpson, Aman P. Peake, and W. H. Harriman, who were said to have taken an unusually large profit for their services, but it was not known that any blame attached to the present management of the Company, A. B. Wolvin and associates. McAlpine claims that he was deceived, and that there was another big profit-sharing after the property and Company passed out of the hands of Simpson and his associates. He charges that the Blackrock mine, which was turned into the Company for several million dollars, was not paid for by the promoters, who are the present owners and the original stockholder and the property is not owned by the Company. The property is capitalized at $6,000,000, but in an annual statement filed for record with the Secretary of State the Company values its property at $8,000,000, and says that more than $2,000,000 were actually paid for the property. McAlpine is trying to prove that. McAlpine was one of many persons taken in “on the ground floor” by the promoters, paying $4 per share for the stock; they could not dispose of its treasury stock, and it became necessary to issue $50,000 first-mortgage bonds in order to raise money to pay options coming due, and to provide a development fund. From the start the Company has been badly managed, and the result of two years' work and the expenditure of much money is an addition of 700 ft. to the Blackrock shaft, which has been sunk from the 500 to the 1,000-ft. level. The Blackrock...
has a large vein, but it has never produced anything but silver, and the silver deposits were practically worked out years ago. The present Company is sinking for copper and silver, and the new miners and the operators from the 500-ft. level down. The Anaconda mine, which was first mined for silver on the upper levels and then turned into the richest copper mine in the world, yielded good copper returns at the same time, though the ore was not treated for its copper content. It is different with the Blackrock; that never yielded copper. The other developed claims in the Blackrock group, like the Nighthawk and Raymond, have also been excludually silver producers.

Operations have been resumed on the Ticon mine by James A. Murray. The shaft has a depth of 500 ft., but the work is being done on the 300-ft. level, where a winze has been sunk to the 500-ft. level. The Ticon is between the Bell of the Anaconda Co., and the Speculator of the North Butte Co., both good copper producers.

The State School of Mines, situated at Butte, has installed a small sampler and plant for making smelting tests. The school will treat ore free of charge.

The life of the Butte Central & Boston Copper Corporation seems to be drawing to a close. At a meeting of creditors in a bankruptcy proceedings in Butte claims aggregating $158,000 were accounted for, and of that about $50,000 are preferred, suit having been brought on them four months prior to the beginning of the bankruptcy proceedings. A trustee in bankruptcy will be appointed in a few days.

The strike of coal miners in Wyoming may have a serious effect on mining and smelting operations in Butte and Anaconda. Ninety per cent of the coal used in Butte comes from the mines in Wyoming, which are now shut down. A supply sufficient to run the companies about six weeks longer is on hand, and this is being augmented by shipments from Montana mines, but the latter cannot furnish all the coal needed. The Amalgamated Co.'s principal source of supply is at Diamondville, Wyo. It is possible that the Montana coal miners will become involved in the trouble, as their contracts with the operators will expire October 1. They are demanding a renewal of the present contract, while the operators insist on changes and reductions.

**SALT LAKE, UTAH.**

The August production of copper for Utah ran close to 8,000,000 lb. Actual figures are difficult to obtain; nevertheless, the foregoing is approximately correct. The Garfield smelter of the American Smelters Securities Co. is credited with 6,500,000 lb.; the Yampa in Bingham canyon, with 800,000 lb. of blister copper; while the Independent smelter near Ogden turned out 150,000 lb. of matte, which is shipped to the United States Smelting, Refining & Mining Co.'s refinery at Chrome, New Jersey. Practically no ore is being received at the Garfield smelter now, other than that coming from the three principal customers of the plant; namely, the Utah Copper, the Utah Consolidated, and the Newhouse mines. Because of the difficulty experienced in treating the fine concentrate from the Garfield concentrators, the Boston Consolidated, as I have stated in another letter, is not sending its mill product to the smelter at the request of the management of the Garfield plant; but is permitted to draw on the smelting company to the extent of 85% of the assay value of the ore, final settlement to be made after the first of January on the basis of prevailing copper prices at that time. This plan is in accordance with an agreement which was entered into.

The showing made by the Boston mill in August was a gratifying one, and has created much favorable comment. While the Utah Copper Co. has released no figures as yet on the result obtained at its plant during the period, the impression is abroad that the balance has been slightly in favor of the Boston Consolidated. Anyway, the Boston mill made an average extraction of 71.8% and the milling costs did not exceed 50¢ per ton for the treatment of 25,000 tons of the Bingham porphyries, which averaged 1.8% copper, and yielded a concentrate averaging slightly above 21%. The behavior of the two Garfield concentrators will no doubt be watched with keen interest during the few next months. One of them, the Utah Copper, is equipped with gyratory crushers and Chilean mills; the Boston Consolidated employs gyratory crushers and Nissen stamps, and the ore treated is identical. A feature of the Boston mill which appeals to the observer is its simplicity, leading to the conclusion that the cost of maintenance will be low.

The Yampa smelter in Bingham canyon is producing 15 tons of blister copper per day, which means that the monthly output will aggregate from 900,000 to 1,000,000 lb. monthly. The new equipment installed last month, which includes a converting plant, is working satisfactorily. A shipment of blister copper made a few days ago assayed 98.5%, besides containing from $175 to $200 per ton in gold and silver. Utah Consolidated continues to produce the tonnage allowable under its contract with the American Smelters Securities Co., which is 500 tons per day. The question of a five-year contract with the smelter has not been definitely settled, but probably will be this month, and on the outcome depends whether the Utah Consolidated Co. will proceed to carry out its plans to build a smelter in Tooele county. On the basis of 13% copper the Company should be showing the largest profits per pound of copper of any producer in the United States, or a profit of 74¢ per pound; that is, after crediting precious metal values against the cost of copper.

Regular monthly dividends will be posted this week by the May Day, Colorado, and Uncle Sam Consolidated Mining companies. A quarterly distribution will also be ordered by the Silver King Coalition Mines Co. A consolidation of the Skytark Copper Mining & Milling and the Wasatch Mining & Milling companies has been effected and the Utah-United Copper Co., organized to take them over. The new corporation has strong backing and proposes a vigorous campaign of development. The properties involved in the transfer are in the Beaver Lake district in Beaver county. One furnace of the new Tintic smelter is in commission and the second one will be within a week. Equipment for two additional lead furnaces has begun to arrive.

![Map of Utah](image-url)
Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Safety-valves of the lever type should have an opening of 1 sq. in. to every 2 sq. ft. of grate surface in the boiler. 

Milk of lime is formed by slaking lime in an excess of water. It is used for many manufacturing purposes, notably in the textile and tanning industries.

Old paint brushes may be effectively cleaned by first soaking in hot kerosene and then cleaning in a mixture of one part of acetone and two parts benzole, or coal-tar naphtha.

Handling plate-glass by lifting-magnets has been successfully accomplished by placing the magnets against the plate of glass, on the opposite side of which is a flat plate of iron or steel.

Dry batteries may be re-charged by soaking in a solution of sal-ammonia for 48 hours, if a dozen or so 1⁄2-in. holes be first drilled through the zinc shell. These holes may later be plugged with hard soap.

Abandonment of a mining claim is a question of fact, and the fact is to be found in the intention. If, after doing his annual labor, a miner should deliberately quit his claim with the expression of his intention not to return to it, or should give permission to others to occupy it as their own, such manifest proof of intent would establish abandonment. Ceasing to work because the ore is not salable does not constitute abandonment.

Simpson's one-third rule gives the area of the surface lying between an irregular curved boundary and a straight base-line. The rule is as follows: divide the base-line into an even number of equal parts and erect ordinates at the points of division; then add together the first and last ordinates, twice the sum of all the other odd ordinates; multiply the sum by one-third of the common distance between ordinates, and the product is the area.

The azimuth of Polaris at elongation is not the same as its polar distance, since the former is a horizontal angle. The azimuth of any star for a given point may be calculated by the following formula: 

\[ \sin A = \sin D \div \cos L, \]

in which \( A \) is the azimuth, \( D \) the polar distance of the star, and \( L \) is the latitude of the place of observation. The mean polar distance of Polaris for 1908 is 1° 11' 03.71", and for 1909 it will be 1° 10' 45.07".

Longitude is determined by a comparison of local and standard time. Local time may be determined by means of an ordinary transit to the nearest second, and if a good watch, whose rate is known, is used for comparison with standard time sent by the telegraph companies, the longitude should be accurate within 15 seconds. However, for the purposes of the ordinary determination of meridian by solar or stellar methods, longitude can be obtained with a sufficient degree of accuracy from a good map, provided, of course, that the geographical position of the place of observation be known. The U. S. Geological Survey publishes maps on the scale of 1 in 125,000, and the longitude and latitude may be easily sealed from such maps to the nearest 15 seconds.

Acceleration of gravity is not of constant intensity over the earth's surface, but is greater at the poles than at the equator, and is also greater at sea-level than at high altitudes. The following formula gives \( g \) in feet for any latitude, \( l \), and any elevation, \( e \), in feet, above sea-level:

\[ g = 32.0894(1 + 0.0052375 \sin^2 l)(1 - 0.0000009957e). \]

The greatest value of \( g \) (32.258) is at the sea-level at the pole, and the least value (32.059) is on high mountains at the equator, and the mean of these extremes (32.16) is commonly used as an average figure.

The horizontal hair of an engineer's transit should be in the plane of motion of the optical centre of the objective. If this condition is not satisfied, the line of collimation will change with every change of the object-glass, rendering the instrument useless for leveling, or for measuring vertical angles. This adjustment is not usually included in text-book discussions of adjustments of transits. Nevertheless it is an important one in adjusting every transit which is to be used for anything except the measurement of horizontal angles. To adjust the horizontal hair, drive a stake near the instrument and read a level rod upon it; then, without moving the telescope in altitude, read a rod upon a second stake 200 or 300 ft. distant. Reverse in altitude and azimuth and bring the telescope to the former reading upon the first stake; then read upon the other stake. If this reading is not the same as before, correct one-half the difference by moving the horizontal hair. Repeat the process for a check.

Lithium, the lightest of the metals, is used in commerce, chiefly in the form of the chloride and other salts, as a medicine. These are beneficial in gouty affections, on account of the fact that lithium salts react with uric acid, forming extremely soluble urates, which are readily eliminated from the system. The principal sources of lithium are lithium mica, or lepidolite, a translucent mineral of pearly lustre, having a very complex chemical composition, and spodumene, which is a simple silicate of alumina and lithia. Lepidolite contains from 4 to 5% of lithia (that is, lithium oxide), while spodumene contains from 7 to 8%. These minerals have been found in such quantities in San Diego county, California, that the market is over-stocked, and will probably remain so for years. Amblygonite, however, could be disposed of. This is a fluo-phosphate of alumina and lithia, containing 4.8% of phosphoric acid and 10% of lithia. It forms coarse crystals of pearly lustre, and usually pale-green to bluish color.
Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

The Ethics of Technical Writing and Technical Writers.

The Editor:

Sir—Rezongador, in your issue of August 29, naively suggests that technical writers should make their information as detailed and as truthful as possible. Who are the technical writers? There are those whose work is a labor of love, who carry on investigation from the pure love of discovering the truth for its own sake, who collect their information in the laboratory or works, and who are free to publish what they are willing to publish without mental reservations.

There are those who admit that it is the duty of all, if they can, to add to the general store of knowledge, but who would never publish anything except at the solicitation of the technical editor who may think they are in a position to know something of general public interest, and will then use his persuasive powers to get the information for the benefit of the public. There are others who are possessed of the passion for writing and the vanity of the notoriety of publication. There are others again who deliberately write for the purpose of self-advertisement, and to keep their names before the public. What is to be the attitude of the student or layman or constant reader before the chalk and blackboard of these professors, quasi professors; before the man who loves to be the first and loudest speaker everywhere and does not wait for an invitation, and before the man in the back seat who has been spied out by the chairman presiding over the meeting and called to the platform.

It is suggested that the information should be as detailed as possible. One is privileged to assume that the readers of a technical journal know something of the subject, and is therefore justified in avoiding obvious and rudimentary detail. He should not doubt give all the details he can which are not obvious and rudimentary, and especially those which would serve to illuminate the presented facts on more sides than one, if such details exist. That he should believe all his statements to be true, and not conceal anything that he fears might throw doubt upon them, goes without saying. What advice would we give to the student about the faith he should place in published technical statements? I believe that the final lecture of every professor on dismissing his students should have for its subject ‘Efficiencies.’ It should warn the student that these may never be 100%; that they may be very much less. He could give many illustrations, and would be justified in pointing out that published efficiencies are generally too high. The yields are generally over-estimated and the losses under-estimated, not from any desire to deceive, but because a man describing a process will be more apt to pick out for illustration a good period than the worst, one that is above rather than below the average. The greatest danger that besets the student in his entrance years into practice is a too great confidence in published ‘efficiencies.’

Rezongador knows this as to certain published milling results. We know this as to almost all classes of published results, electrical, mechanical, and others. The student should be trained to adopt toward all such results, even those to be found in the text-books and the manufacturers’ catalogues, an attitude of respectful but firm criticism, recognizing the results as entirely correct and honest so far as they go, but that they do not go so far as average practice year in and year out, but represent a practice unaffected by accidents, carelessness of employees, delays of starting and tuning up a plant, training of the personnel, strikes, and a thousand other causes, like the fouling of boiler-tubes with scale, the uneven wear of rolls, the leakage of the piston, and the weakening of the insulation.

Technical writers should be careful to state, when they can, their opinion upon the efficiency-results they publish; whether they are average or otherwise. In the case of milling tests, if the heads have not been systematically and properly sampled, that should be emphasized. I remember a story of an old game-warden who, when breech-loading shotguns were being introduced, was asked for the first time to look down the opened shining barrels of the new gun. He remarked that if they could do that with the muzzle-loaders there would be some ‘awful revelations.’ If we could look into tailing dumps, slag dumps, and efficiencies of plant and machinery all around, there would be some awful revelations.

ESCRUTADOR.

Gold-Dredges, Large and Small.

The Editor:

Sir—Noticing the editorial in your issue of August 15 on ‘Gold-Dredges, Large and Small,’ I note that you make the following statements: ‘It is interesting chiefly as showing that a need exists for economical gravel excavators of small cost and moderate capacity, and that meagre attention has been paid to it by engineers of training adequate for reaching successful solutions of the problem.” Again you say, “the attention of engineers might advantageously be directed to the design of small as well as large gold-dredging appliances.”

I desire to call your attention to a form of gold dredge designed by me for the New York Engineering Co., which meets these requirements, as I have fully appreciated the long-felt want for a small gold-dredge that would have a moderate capacity of about 1000 cu. yd. per day, and that would be an efficient and practical operating mechanism, and yet not be so expensive in first cost as the regular standard type now on the market.

This dredge is of the regular California type in form, embodying every improvement and detail as employed in the larger sizes, only it is equipped with smaller buckets, and consequently all other parts are lighter. The main feature, however, is that it has a
steel hull, and all of the gantries and superstructure are of structural steel, that is, built up from I-beams, angles, and channels, in the form of latticed girders, in the same way as the steel skeleton of a modern office building. The hull is made up of angle-iron frames, thoroughly braced and stayed, and of similar form to the frames used in wood-hull construction, and the outside or sheathing is of sheet-steel. The gantries and superstructure are all of the latticed-girder type, and form a Howe-trussed girder extending the full length of the dredge, thus retaining the modern form of bracing and superstructure that is now employed in the construction of large dredges with wood hulls. This steel form of construction has a most important bearing in cutting down the final cost of the complete dredge, as described hereafter. This dredge has a bucket-line of modern type equipped with buckets of 2 cu. ft. capacity, of the same style and proportionate weight as the latest California buckets, that is, they have a heavy cast-steel base, with wrought-steel hoods, and manganese-steel lips. The upper and lower tumblers have renewable wearing faces and the lower tumbler runs in waterproof bearings; in fact, all of the features of the later type of dredges are utilized. An interesting feature is the extremely low cost of the dredge when completed and ready for operation, especially in inaccessible regions, where all of the timber required in the construction has to be brought from the outside. This is generally essential in the tropics, owing to the inefficient facilities for getting out the 100,000 ft. of lumber usually required, and often because the native timber is not of the right quality and character for this kind of work. Thus the large saving in final cost is due to the fact that the dredge is built completely of steel, and is assembled in the shop, and all parts are drilled and fitted to place. The only work involved is the riveting together of the steel work, and the bolting of the machinery in place. This requires very little skilled labor and only a small amount of common labor, and does away with the ship-carpenters and millwrights usually required in the building of a wooden hull machine.

The second important saving in costs is in the items of freight and haulage, as the steel hull weighs only one third as much as the wood hull. The freight and haulage charges with wood construction are usually a large item, and in some instances have been known to amount to as much or more than the initial cost of the machinery. The low final cost of this dredge is not attained by sacrificing quality or weight in the machinery, as this is fatal in dredging practice, but is attained by the saving in freights and haulage, and especially in the large amount of labor usually required in the assembling and erecting of a dredge with a wood hull. This dredge is not designed to operate in hard cemented gravel containing large boulders, as much ground can only be handled by a heavy dredge, with larger buckets. It is intended as an equipment suitable for a piece of ground containing a limited amount of gravel that will not warrant a more expensive equipment. The cost per cubic yard of material handled by this dredge will naturally be higher than that of the larger machines. Nevertheless, it will fill a need and provide a means for exploiting placer properties that have not been worked heretofore owing to the lack of such an apparatus.

New York, August 27.

Separation of Slime.

The Editor:

Sir,—In a letter appearing in your issue of July 25, H. T. Willis discusses the question of the 'Separation of Slime,' in connection with H. G. Nichols' article of April 25. From the point of one who is greatly interested in the subject, it would seem that as a reply to a contribution bearing on its face the evidence of very careful and exhaustive work, Mr. Willis' remark that other metallurgists have embodied all the principles alluded to and have carried the subject still further, in another process, is somewhat inadequately brief. Mr. Willis' subsequent remarks lead one to suspect that possibly he has a different process in mind, for instance, his contention 'that enormously greater amounts of solution required to be pumped' suggests that he has not quite grasped the salient feature of Mr. Nichols' process, and further, his remarks amount 'depth and diameter of vat' lead to the conclusion that he is thinking of a continuous decantation method, a very different idea. It would certainly seem, moreover, that Mr. Willis is in error in regard to pulp acting like a dense liquid. Mr. Nichols has dealt with this point in his article appearing July 11, page 54, in the MINING AND SCIENTIFIC PRESS, and has pointed out the great importance of avoiding this mistake.

The question of free settlement, and all that it implies in practice, requires careful thought. Let it be understood that the scope of the present discussion is in connection with one phase of free settlement.
R. H. Richards has given us most important data regarding free settlement, as affected by size and specific gravity of particles, and his deduction regarding the law of viscous resistance must enter into any consideration of the subject. The particular phase referred to is, of course, that in connection with retardation due to accumulation, and thus far it has not been, apparently, studied with regard to size and specific gravity of the solid particles. Whether such a study would be of practical value is not at the moment suggested, but certainly a field for investigation might be possible along these lines, for instance, to what extent it is an advantage to have varying sizes and specific gravity of particles in a settling-charge, as finely ground quartz in clay slime?

A charge of any density may be tested for free settlement by using the simple apparatus shown in the photograph reproduced herewith (which is Mr. Nichols’ Fig. 2, slightly modified). Here, in place of a stop-cock, a piece of flat rubber is drawn up against cork-connecting bottles. Any water may be drawn from the upper vessel, and a known charge introduced. In the photograph the pulp which settled contained 30% of the finest clay, and the actual time between the introduction and the exposure was 6 seconds. Owing to the difficulty of securing such a photograph, the principal feature to be noted is lost. The clotted slime, as it accumulated, could be plainly seen falling through the cloudy solution, but could not be photographed.

Cornish Pumps of New Design.

The Editor:

Sir—I have read with interest E. P. Jones’ letter in your issue of January 18, and also the letter from ‘Old Timer’ of March 4, on the subject of Cornish pumps. The pumps described by Mr. Jones, and of which you produce an illustration, can hardly be called of ‘new design,’ seeing that that particular type has been in use considerably over twenty years. It is an improvement on the original Cornish type with ‘H-piece,’ but it is not suitable for deep lifts. The valves also are only suitable for light pressures, of not more than 250 ft. The tendency nowadays is to increase the lift on each plunger, thereby decreasing the number of parts, and reducing the cost both in machinery and underground excavation. By carefully designing the valve-boxes, and by using an improved type of valve, this has been made possible and lifts of over 1000 ft. are not uncommon.

The old single-cylinder type of Cornish engine was the most economical pumping-engine built when worked at the steam-pressure (40 to 50 lb.) in vogue in the middle of the last century.

The increase in steam-pressures has sealed the doom of this type of pumping-engine, for with the Cornish engine it is not possible to cut off earlier than 1/4 to 1/8 stroke, owing to the great stresses set up in the pump-rods. The Cornish cycle is an ideal one, and particularly adapted to metalliferous mines, as the single line of rods takes up but little room in the shaft. The use of higher steam-pressures introduced various types of engines for pumping purposes, one of the commonest being the compound rotative engine coupled to the pump-rods by gearing and angle-bobs. This type has not proved a great success, owing to the heavy cost of maintenance, to its reduced efficiency caused by the gearing, and to its inability to adapt itself to varying amounts of water. This latter fault is particularly objectionable during sinking operations.

A description of the plant at the Waihi mine may be of interest. There are three Davey compound Cornish engines, working with a steam-pressure of 150 lb. per square inch; the largest is capable of raising 1500 gal. of water per minute from a depth of 1600 ft. Each engine has a high and low-pressure cylinder. Steam is used in the high-pressure cylinder on the Cornish cycle, and is then transferred to the low-pressure cylinder, where the same cycle is also gone through. By this means the economy due to the use of high-pressure steam is taken advantage of, and in the particular engine under notice, steam is expanded 14 volumes, as compared with 4 or 5 in the old type. The water-load is also increased from about 16 to 20 lb. per square inch in the old type, to 30 lb. in the new type (referred to the low-pressure cylinder). The engine is fitted with plungers 23 in. diam. by 12-ft. stroke, and arranged for an initial lift of 700 ft., the plungers below this being placed every 300 ft. apart, to suit the levels. There are five suction and three delivery valves on each pump, the valves being of the double-beat type, with gutta percha beats. The lift of the valves is 1 1/4 in. and rubber rings around the spindle cause the valves to close quickly and prevent jar. The valve-boxes are of simple design, absolutely free from the defects of the old H-piece type, and changing of the valves is accomplished very quickly. We have used a bucket-pump (17 in. diam.) on one of these engines with a lift of 330 ft. with complete success, the bucket-rings being of gutta percha, and the valve of the double-beat type with gutta percha beats.

The combined efficiency of the plant, that is, 100 times water-horsepower divided by indicated horsepower, in ordinary working is about 82%, and the steam used in ordinary every-day running is about 17 lb. per indicated horsepower-hour. These figures are unfair to the engine, as it is at present not running up to its capacity, and it should, I think, come well under 15 lb. of steam per indicated horsepower-hour on full load.

The combined efficiency of any other type of heavy mining plant is less than this. With a geared engine we cannot reasonably expect to obtain a greater combined efficiency than from 70 to 75%; with electrically driven three-throw pumps about 50%; and with electrically driven turbine-pumps anything below 50%, according to the load factor. The above remarks refer to mine drainage. In a waterworks plant these figures can be much improved upon. Take the case, for instance, of the triple-expansion Hathorn-Davey engine at the Rand waterworks, where the duty was 172,000,000 per 1000 lb. of steam,
and the steam-consumption 10.3 lb. per indicated horsepower-hour, the head being 975 ft. in one lift. This type, however, is not suitable for mine-drainage. With the pumps described above no air-vessel has been provided, and it has not been found necessary to fit one, the pump being perfectly quiet and free from that objectionable jar so common in mine-pumps worked by rotative engines. As regards economy, the compound Copper type can hold its own against any other form of pump. Take the figures as 15 lb. of steam per indicated horsepower-hour, and the combined efficiency of 80%, then the steam used per horsepower-hour in water lifted equals 18.75 lb. With electric three-throw pumps and steam-generating plant, and a combined efficiency of 50%, in order to equal the Cornish pump the steam engines would require to have a consumption of only 9.37 lb. per indicated horsepower-hour, which I need hardly say is at present impossible under ordinary working conditions. The cost of repairs, labor, oils, and stores is also heavier with the electric pump. The electric turbine pump need not seriously be considered, for unless the water pumped is fairly constant it is far below any of the above types on the score of economy.

W. Percy Gauvain.

*Cloths.

The costs of supplies applying above as follows: Hydrochloric acid, $4.30 per barrel; sludge, 0.005c. per lb.; lime, 0.005c. per lb.; zinc, 0.06c. per lb.; labor, $3.50 per 8-hr. shift; power, $0.50 per mechanical horsepower per month. One suit of filter-cloths lasts one year; for 24 presses, cloth-consumption is two suits per month, or 1c. per ton of slime treated.

**Method of Presenting Screen-Analyses.**

The Editor:
Sir—I have read the article by G. H. Rotherham in your issue of September 5, describing the 'Milling Plant of the Montana-Tonopah Mining Company,' and it occurred to me that a suggestion concerning a method of stating the results of sizing-tests might not come amiss. The cement-tester, in stating the fineness and gradation of sizes in sand, has similar data to submit on this point as did Mr. Rotherham. I believe that, while in no sense new or original, the following method has much to recommend it in the way of conciseness and perspicuity. For the sake of definiteness, take the example of the pulp from the battery as given by Mr. Rotherham. Its screen analysis may be conveniently expressed as follows:

```
2.5% 30 25.5 60 48.5 80 61 100 163 200 45.47
```

in which the larger figures represent the sieve-numbers, and the smaller upper figures represent the percentages passing and caught upon each sieve, according to whether the latter follows or precedes the sieve-number. This simple scheme gives most of the advantages of a graphical presentation, and entails none of the necessary drawing and reproduction.

**Homestake Slime-Plant Costs.**

The Editor:
Sir—I enclose tabulated and analyzed Homestake slime-plant operating costs for the month of March 1908, which was a typical month. I trust it may prove of interest to your readers.

C. W. Merrill.
San Francisco, August 14.
DREDGING IN THE YUKON.

Written for the MINING AND SCIENTIFIC PRESS
By T. A. RICKARD.

(Continued From Page 293.)

Apart from economic conditions, which vary all over the world, the distinctive feature of dredging practice on the Yukon is the necessity for overcoming the frozen condition of the ground. This is a geologic frost as distinguished from the seasonal frost; the first is the sequel of a Glacial period, that is, a time when the summer thaw was unable to overtake the winter frost; the second is due merely to winter cold. The seasonal frost, as measured on ground that has been thawed in summer, ranges from 3 to 5 ft., but the geologic frost extends to a depth of 230 ft., if not more, wherever the ground is wet, as in valley-bottoms. On the other hand, the warmth of the short summer, lasting 4 to 4½ months, will thaw the ground to a depth of 4 to 7 ft., according to local conditions, the chief of which is the nature of the surface-covering. In two seasons the frost in a gravel deposit may be conquered by the seasonal thaw to a depth of 10 to 22 feet.

The Northland is covered by a blanket of moss and loam due to the decay of vegetation. This overburden is called 'muck' by the miners because when it melts it runs like thin mud, for it is composed of 25 to 40% organic matter and 60 to 75% ice. When either the summer sun or artificial heat strikes this black blanket, it disintegrates and is readily floated on the running stream. Being a mixture of organic matter and ice, it makes a perfect insulator against heat and protects the underlying frozen ground from the warm air of summer. The thickness of this frozen muck varies from a few inches to 40 ft., the maximum being in gullies where it has accumulated by sliding from adjoining hillsides. Two feet is an average thickness. In summer, it melts; in winter, it freezes solid.

It is obvious that before the seasonal thaw can become effective, the blanket of moss must be removed. This is done naturally by freshets and by meandering streams; it has been done in a general way as an incident in ordinary mining operations along the creeks, and it will be done systematically both by ground-slicing and also, much more rapidly, by hydraulicizing. Where time is not an immediate factor and where bed-rock is not more than 15 ft. deep, a gravel deposit can be thawed to bed-rock in two seasons by simply removing the cover of moss and loam so that the summer heat may get an opportunity to penetrate. But, on the other hand, where dredging operations cannot wait for such a slow method, or bed-rock is deeper than 15 ft., or where old workings exist, it becomes necessary both to accelerate and to perfect the thawing process by the aid of artificial methods. This is done by the application of steam.

By introducing steam into the frozen ground, the ice is a non-conductor; rock is relatively a good conductor; therefore, the less water the gravel contains, the more easily it is thawed. The stones retain the heat imparted to them so as to radiate it slowly into the surrounding mass. The method of thawing by steam was exemplified on claim 90 Below Discovery on Bonanza creek, just above the No. 6 dredge of the Yukon Gold Co. The boiler-plant consists of two boilers rated at 150, and one rated at 75 hp. These are fired with wood at $8 per cord delivered, the steam-gauge registering a pressure of 150 lb. per sq. in. in the case of the larger boilers, and 100 lb. pressure in the small one. The main pipe-line is 3½ in. diam., and is carried within boxes packed with sawdust as an insulator. All the pipes are wrapped in ‘asbestos’ covering. The branch pipes approaching the ground to be thawed (at 300 to 400 ft. from the boiler-plant) are 1½ in. diam., also insulated and boxed. At intervals of 8 ft., openings in the pipe connect through nipples with short lengths of hose. This hose is 3/8 in. diam. and 17 ft. long; it must be long enough to reach the heads of the ‘steam-points’ when they are being swung into position, and to allow latitude in twisting the ‘points.’ The ‘point’ is a ‘hydraulic’ steel pipe 1/2 to 3/4 in. diam., in lengths of 14 to 20 ft. Each hollow rod is provided with steel ends, that is, both the head, which is hammered to drive the point into the ground, and the end penetrating the ground. The point itself, or advancing end, has an orifice 5/16 in. diam., and through this the steam enters the ground. By the time the steam reaches the place where it escapes into the gravel the pressure has sunk to 25 lb. per sq. in. It must be noted that the pressure at the point is directly dependent upon the number of points, and the aim is to keep it at 25 pounds.

In starting a point it is customary to take a 1¼-in. steel bar and drive it down with an 8-lb. sledge-hammer until frozen ground is struck; then the steam-point itself is introduced, the bar having been withdrawn. The top or head of the point is pounded by one man with a 4-lb. hammer, and at the same time a twist is imparted by a wrench held by another man. This is done at intervals as the ground is softened by thawing, the man in charge proceeding from one ‘point’ to another in rotation. The rate of thaw is about 2 ft. per hour. If the point resists to sink, it is allowed to rest for a while, and then if no progress can be made in the usual way, it is inferred that an obstruction, such as a boulder, exists. The steam-pipe is pulled out of the hole with the aid of a lifting-jack and a solid steel bar is introduced; this is then hammered with a sledge so as to penetrate the obstruction or push it aside. If the incompetence of the steam-point is due to the clogging of the orifice through which the steam is emitted this is indicated by condensation at the head, and also by listening for the flow of steam through the hose. The heads of the points are strengthened, so as to receive the blows of a hammer, by a sleeve (or driving-head), fitting the elbow to which the hose is attached. A special clamp is now used instead of the Stillson wrench. I noted that frozen
ground was struck in most cases at 6 ft., this being the depth to which the seasonal thaw had progressed after the moss had been removed.

This method of thawing the frozen ground has been described in some detail as an interesting development of local practice; but it is a temporary procedure. As soon as sufficient water is made available by the completion of a main ditch-system, it is intended to strip the covering of moss by the use of water under high pressure. The ditch and pipe-line of the Yukon Gold Co. is now approaching completion, and the water will be ready for stripping early next season. Thawing will be discarded at the close of next season, except in isolated spots where the water cannot be used advantageously. The method of using water in preparing the ground for dredging will be as follows: First, stock-lines will be laid along the edge of the creek carrying water under high pressure, tapped from the main trunk line. The moss and muck will be stripped by 'piping' (that is, the use of a large volume of water under pressure), driving from both sides to a longitudinal cut, down the centre of the claims. See Fig. 1. This work will be carried forward about two miles ahead of the dredges. When the ground has been stripped, the water will again be applied (at the lower end first), so as to cross-cut the gravel with trenches at intervals of from 20 to 50 ft. The effect of this exposure of faces of gravel to the air is to accelerate the natural thaw. After the cross-trenches have been made, the longitudinal trench will be deepened so as to drain the entire area. The depth of the trenches, and the extent to which this work is carried, will depend upon the depth to bed-rock and the rate of thaw. See Fig. 2 and 3. Experience thus far indicates that when the stripping has been completed, not much trenching is necessary to carry the thaw to bed-rock when the gravel is not more than 18 or 20 ft. deep. Each successive season will extend the thaw farther, so that the depth and amount of trenching will depend upon the nearness of the dredge. By this method, the total cost of preparing the ground for dredging should not exceed 5c. per cu. yd., for there is no installation and maintenance of sluices, and many of the other expenditures incidental to hydraulic mining are lacking. The actual work of mining is done by the dredge; the amount of ground moved in the preliminary operation being small, compared to the yardage dug subsequently by the dredge itself. By thus making the most of the natural thaw, and preparing the ground for rapid dredging, the total cost of mining the gravel should not average more than 20 to 25c. per cu. yd. The result obtained with artificial thawing in advance of dredging actually shows a cost of 19 to 35c. per yd. The more the natural thaw is used to fight the natural frost, the smaller the expense will be, and the less the final cost of operation.

As a matter of interest, the following data concerning the operations of the No. 6 dredge may be quoted: The width of dredgeable ground, reaching from claim No. 88 Below Discovery on Bonanza creek to No. 104, ranges from 500 to 1300 ft. The depth to bed-rock averages 16.7 ft. The bed-rock itself is sericite-schist, with quartz stringers, decomposed so as to be dredgeable to 4 or 5 ft. deep. The gravel is small; immediately above bed-rock, where the stones are largest, the size is rarely over 6 in., with a few boulders that attain a weight of 100 lb.
apiece. The length of campaign here is one-third of a year, and the dredge is expected to be in service for a period 1½ times as long as in California, that is, the actual working time is one half that of a dredge working at Oroville. Depreciation in the Yukon is based on a service of 12 seasons, equivalent to 5 years of actual operation; in California it is 10 years.

During the 22 days of July that had elapsed up to the date of this writing, the No. 6 dredge had dug 51,952 cu. yd., from the start of work. The total cost was $11,728; the total yield was 2718.48 oz. gold, worth $44,281; the operating profit was $32,553. In the costs are included $1443 for labor, $50 for repairs, $150 for supplies, $1500 for depreciation, $1752 for selling charges (including also tax, express, and treatment) on the gold. Power-cost, $1500, this being based on 300 hours at an average load of 200 kw. hr., or 60,000 kw., at 2.51c. per hour. Thawing to the amount of 4086 sq. yd. cost $4168. Repairs and supplies are low as compared to an average operation. If this item is increased by $1500 to $1800 per month for the season, the extra cost would be, say, 2½c. per yard. The allowance for repairs and depreciation together is then $3500 to $4000 per month.

It is noted that the thawing by steam-points covered 4086 sq. yd. of bed-rock at a cost of $4168, to which must be added the preliminary sluicing-cost of $800. Of the total yardage dug by the dredge, only 56% required artificial thawing; in consequence, the net cost of thawing was only 9½c. per cubic yard dredged.

The work of the 22 days showed a return of 85.3c. per cubic yard; the cost was 22.6c. and the gain 62.7c. Adding 2.5c. more for repairs, the cost becomes 25.1 and the profit 60.2 cents per cubic yard. It is interesting to state that the estimate based on the examination of this ground was 60 cents gross per yard. The actual return thus far affords an encouraging result; for the cost is as estimated, while the profit is greater. It must be remembered that the No. 6 dredge is a new machine, just put into operation. As the season progresses, the capacity will be increased; it ought to be at least 80,000 cu. yd. per month, as against the rate of 70,000 recorded for the period reviewed. At Oroville, dredges of the same type are digging from 120,000 to 150,000 cu. yd. per month in ground yielding 12c. per yard at a cost of 5c. per yard.

At the present time the Yukon Gold Co. has five dredges in operation and two more nearly ready to start. The economic results, so far this season are uniformly good, and compare favorably with the original estimates. Difficulties due to frozen ground are almost negligible; the troubles that proved so annoying last year were due chiefly to inadequate equipment. While some artificial thawing by steam will always be necessary, in spots, and while such thawing is costly, the proportion of ground requiring the use of steam-points will be steadily reduced. The application of water under pressure, as already described, will become an important factor in diminishing the expense of preparing ground for dredging. On the whole, it is apparent that frozen ground is not the terror it has been represented to be, on the basis of the first experience with dredging in this region.

The Canadian Klondike dredge showed a seasonal cost last year of 16½ cents per cubic yard, digging ground that needed no artificial thawing. I am informed, on good local authority, that the Bonanza Basin dredge, at the mouth of the Klondike river, is now doing well, in rich ground. The dredge at the mouth of the Forty Mile river is also said to be working at a profit. The Yukon Gold Co.’s dredges are working at a total cost, including thawing, of 19 to 35c., and the expense will be reduced next season to an average of, say, 20 cents. The gravel is rich and patchy, as rich gravel always is; but there is every reason to believe that some of the claims on Hunker and Bonanza creeks will give yields constituting a new record in this branch of mining.

On the whole, the prospects for dredging in this region are vastly better than they were a couple of years ago. Where failures have been made, they were due mainly to light machinery of inferior design, hindered by inadequate equipment, rather than the poverty of the ground or natural obstacles to mining operations.
Five-Foot Steam Dredge, Forty Mile Creek, Alaska: Digs 20 Feet, Shakes 20 Feet, with Capacity of 60,000 Cubic Yards per Month.
ASSOCIATION OF MAGNETITE WITH SULPHIDES IN MINERAL DEPOSITS.

Written for the MINING and SCIENTIFIC PRESS
By John B. Hastings.

(Continued From Page 534.)

W. H. Emmons, describing the Cable mine, Montana, says: "The orebodies of the Cable mine are . . . replacement deposits of contact-metamorphic origin. . . . They cannot be classed as replacement veins or stocks, for their boundaries are approximately cylindrical or rudely spherical, and a single orebody does not extend very far in any one direction. . . . Magnetite is present throughout the ore-zone as large irregular bodies that have apparently no relation to the bedding-planes of the rocks. These bodies are confined to the limestone, and occur on all levels. The magnetite bodies are rudely ellipsoidal in outline, and some of them are at least 100 ft. diam. . . . The ore deposits are large irregular bodies of calcite and quartz, containing a large amount of mixed iron and copper sulphides and iron oxides. These are confined to a long narrow zone of limestone and calcareous shale that trends southward and is bounded by two granite intrusives, the walls of which are steeply inclined, nearly parallel, and from 80 to 360 ft. apart. . . . The original metallic minerals are pyrite, chalcopyrite, pyrrhotite, arsenopyrite, magnetite, specularite, and gold. . . . In most of the ore of the lower levels calcite, quartz, pyrite, and chalcopyrite are interlocking irregular bodies, which apparently were deposited at one time. When a magnet is passed over the crumpled ore, there is nearly always a separation of magnetite and pyrrhotite. . . . The primary ore minerals are pyrite, pyrrhotite, chalcopyrite, magnetite, and specularite, and these are all characteristic of contact-metamorphic deposits. The earthy minerals also characteristic of contact-metamorphic deposits and present in the ore-zone are amphibole, calcite, garnet, mica, and epidote. Calcite is the only one of these which is intimately associated with or is a part of the ore." The mica occurs in fault-planes, and is younger than the magnetite.

About Cable mountain are similar deposits in limestone near the granite contact, and these replacement-deposits, in contra-distinction to those just described, are clearly related to fissures. "Much of the magnetite carries from 20 to 80c. per ton in gold, and at some places it has been prospected with the hope that in depth it will change to a sulphide ore carrying gold in payable grade. The large bodies of magnetite, however, are unquestionably of primary origin, and will continue to be magnetite as far down as they extend. The pyrite ore of the veins alters to limonite and hematite, carrying small grains of magnetite, and nowhere to large masses of magnetite. The presence of the small magnetite grains in the oxidized ore has no diagnostic value, for they are present in the oxidized ore of practically every ore deposit in the Philipsburg area, and a large number of these are ordinary fissure-veins, and in no sense replacement deposits."

The following are three examples of allied occurrence of magnetite in the East. W. Lindgren, writing of the gold deposits of Dahlonega, Georgia, describes the enclosing rock as mica-schist and amphibolite, both thoroughly re-crystallized by hydro-chemical and dynamo-metamorphic action. He says: "Magnetite is present in elongated masses, in places intergrown with pyrite and chalcopyrite. There is no pyrite, but a considerable amount of pyrrhotite, usually intergrown with smaller grains of chalcopyrite." The veins are described as of similar type to those of California and Australia, derived from solfatara waters, following fissures usually corresponding with the foliation of the mica-schist. It seems to be uncertain how much of the magnetite was introduced by these waters, as the magnetite of the wall-rock and some of the veins is seen to antedate the latter, and to have remained stable during their formation.

L. C. Gratton, on the gold and tin deposits of the southern Appalachians, says: "Magnetite occurs in the wall-rock of a quartz vein at the Jones tin mine, and has undoubtedly been formed by the vein-solutions." These solutions deposited gold, pyrite, pyrrhotite, chalcopyrite, and other minerals.

Of the magnetite deposits described above, only those seen by Brooks were thought to be surface oxidation products, in which the magnetite was a secondary mineral. Kemp thought the magnetite in Mexico primary, but deposited earlier than the sulphides which impregnated it. Lindgren, Spencer, Brooks, Gratton, S. F. Emmons, and W. H. Emmons, in the respective deposits examined, also thought the magnetite primary and contemporaneous with more or less of the sulphide, and finally all the authors are agreed that the iron is a foreign constituent, brought up from depth, presumably an emanation from cooling magmas, and as nearly as I can interpret their decision, they think the vehicle of transportation was water. It may have started as a vapor, but probably the resistance to its passage in the poorly defined channels described would so impede it as to allow of condensation. It not only had to convey the ore materials to their present position, but to take up and continue on with the matter replaced.

There should not be any surprise at finding magnetite when its original source is held to be an eruptive magma, as almost any piece of the crystalline rock, even small enough to be microscopically examined, contains magnetite. If there be astonishment, it is perhaps because the iron in precious metal deposits is usually a sulphide. We are apt to think of vulcanism as giving off great quantities of sulphur, and so it does to a certain extent, and in certain places, but it is small when compared with oxygen. This is shown by the constituents of the extruded rocks, which are all oxides. We might think that the sulphur would be driven off by the excessive heat, and not form chemical combinations, but this force is balanced by pressure. It is expelled to some extent as
sulphurated hydrogen and sublimates in free vents, and it is also carried away by the escaping vapors of magmas with the same selective affinity they exhibit for the metals and other metalloids. Its presence in the magma is sometimes shown by the formation of iron sulphides, which have been found to occur quite often as an original constituent of eruptives.

With the presence of an excess of water in magmas or subterranean channels the hydrated iron oxide, instead of the anhydrous, might be expected to form. Van Hise thinks pressure has to do with the result. Magnetite is one of the first minerals to solidify in a magma, but it is not always resistant to vaporous solutions, as shown by Lindgren at Dullahoneg. The same author found it unstable in California in the presence of other ascending vein-waters, so it is but natural that it should be re-dissolved and carried off from the magmas by the solutions. It is significant, in view of their easy solidification, that these iron oxides are absent from the later and cooler stages of salification, and quite common in typical contact-deposits formed by pneumatolytic action. As such vapors carrying sulphur attack the biotite and magnetite of the country passed through, and form sulphides at their expense, it suggests that, given the necessary amount of sulphur, pyrite instead of magnetite would be formed. If there is a lack of sulphur in the ascending solutions, however, copper will apparently first supply itself, then pyrrhotite. (FeS) will form, instead of pyrite (FeS), and when the sulphur is used up, magnetite must form. As illustrative of the lack of sulphur, the native iron in the basalts of Ovifik, Greenland, is possibly a case in point. There iron alloyed with nickel and cobalt has resisted oxidation in its solidification so that it survives as particles of native metal alongside of crystals of magnetite, and both are distributed with the other constituents of the basalt—feldspar, augite, and olivine. As is well known, the iron has also concentrated into quite large masses at the same place, and when first discovered by Nordenskiold in 1870 they were thought to be ordinary meteorites, but this being disproved (1), they have since been sometimes thought original fragments from the dense central mass of the earth.

Magmas need to be regarded as solutions with all the potentialities of chemical combinations, so much so that as fast as minerals solidify they are shoved to one side, into the cooler part. This is the law of differentiation, as discovered by Sorby, and in effect, as the more basic minerals solidify first, plutonics, like slowly cooling slags, are more acid in the interior of their masses. This is well put by J. P. Iddings (2): "The minerals which crystallize in a rock magma result from the chemical affinities inherent in a complex solution of silice, alumina, alkaline earths, and alkalies, including iron, lime, magnesia, potash, and soda, between the various demands of which there must be a mutual accommodation. Hence it is evident that the component minerals of a given rock must be those which, under the conditions attending their crystallization, satisfy all the chemical demands imposed by those conditions." These remarks are equally applicable to the magmatic waters. Probably the greatest differentiation of magnetite known on the continent is that at Iron mountain, Wyoming, lately described by S. H. Ball. This immense deposit of titaniferous magnetite was discovered in 1850 by H. Stansbury, and has been described by Hayden, King, Kemp, and others. It is a true iron dike, 1/2 miles long and 40 to 300 ft. wide, with an average width of perhaps 175 ft., cutting anorthosite. The contact between this enclosing rock and the ore-dike is sharp where exposed, "neither rock having undergone important gradational changes. . . . The iron ore is a black, granular, holocrystalline igneous rock, with constituent grains varying from 1/8 to 1/2 in. diam.; . . . It has a metallic or sub-metallic lustre. Changes in granularity occur in irregular masses or along well defined parallel planes. In consequence of this distribution the rock has at some places an original gneissie structure. The greater portion of the iron is free from mechanical impurities, but biotite, olivine, and feldspar are sporadically distributed throughout its mass. . . . The iron content is fairly high, averaging about 50%, and the most noticeable feature of the ore is its high titanium content. . . . The iron ore and the anorthosite are differentiation products of a common magma, the iron ore having been intruded into the anorthosite after that rock had completely solidified." The sulphur content averaged 0.033% in three analyses, and 1.29% in two others. This means a concentration of about eight into one, from the original gabbros.

COKE-MAKING IN WASHINGTON.

Washington is the only one of the Pacific Coast States in which coking coals are known to occur, according to E. W. Parker, chief statistician of the U. S. Geological Survey. When compared with those of some of the Eastern States, the coking operations in Washington seem of small importance, but they are of interest as establishing the fact of the possibility of making metallurgical coke from Pacific Coast coal. All the coking operations are in Pierce county, in the central part of the State. There are five establishments, four of which made coke in 1907, producing 52,038 tons, valued at $293,019, against 45,642 short tons, valued at $266,977 in 1906. The average price per ton advanced from $4.99 in 1906 to $5.63 in 1907. All of the coal used in coking-making in Washington in 1907 amounting to 53,860 short tons, was washed. Three of the plants used washed run-of-mine coal and one used washed slack.

The Lash steel process, in which finely divided ore is intimately mixed with carbon, a certain quantity of finely divided carboniferous iron, sawdust, and suitable fluxes, and the whole treated in an open-hearth furnace in a bath of molten metal, is one of the most recent inventions. It is claimed that in using the Lash mixture in an electric furnace no bath of pig-iron is necessary, and a yield of 98% of the metallic content of the mixture is recovered.

**DIRE PLACERS OF NORTHERN SONORA.**

Written for the MINING AND SCIENTIFIC PRESS

By F. J. H. Merrill

From the early days of the Spanish occupation Sonora has been one of the chief gold-producing districts in the Mexican Republic, and there is every reason to believe that a part of the Aztec treasures of this precious metal came from this State. Gold-bearing veins are abundant in its westernmost district, which was named Altar from the Jesuit mission of Santa Guadalupe del Altar, founded in the latter part of the seventeenth century. From the superficial decay of these veins came a series of extensive placer-deposits, in which the gold was concentrated by rain-wash in channels, or *corrientes*, now buried below the surface, which have proved to be more important sources of this metal than the veins in this region which have thus far been worked, for the placers represent the concentrated values of hundreds of feet of vein-matter, and therefore a tennage far beyond the production of any or all of the mines thus far operated in the Altar district. As in many other parts of the southwest, there being no supply of water available at low cost for washing the gravel, the deposits are known as 'dry-placers.' These formations occur at other points in Sonora, but have not attained as great an extent or developed as much commercial importance as in the district of Altar. At most places where these deposits occur they consist of two divisions, an upper member of loose material, and a lower member of cemented gravel. The superficial material, being easier to work, has been the object of the earlier operations, and in most of the placer fields has been quite vigorously exploited by primitive methods. The lower member, being a gravel cemented with calcareous matter, has generally been left unexplored until within the last three or four years, when, chiefly by American enterprise, shafts have been sunk in it to a depth of 100 to 150 ft., and the gold has been successfully extracted from the richer gravel of the 'channels' in which the ancient streams concentrated the metal. The superficial loose-gravel is worked by two methods. The more primitive is by the *batea*, or wooden gold-pan. In this, the gold-bearing dirt is placed, and by skillful whirling, and a blast of air from the lungs, the lighter material is winnowed out, leaving the gold and a heavy black-sand, which is further cleaned by the use of a magnet and by careful manipulation.

A more commercial method is by the use of the Hungarian 'dry-washer,' a machine introduced from Europe about 1851. This consists of an inclined table placed over a bellows which is driven by a belt from a wheel turned by hand. The table is a wooden frame, crossed by riffles, and with muslin stretched on its under surface. Through this muslin passes the intermittent blast of air, and the dirt, falling from a hopper at the head of the table, which slopes about 15° from the horizontal, passes gradually down the incline, aided by the periodic shock of the bellows-stroke, the light dust and sand being blown upward and over the successive riffles. As the operation continues, the bulk of the material falls to the ground over the lower end of the table, while the gold, and a small part of the other heavy particles, are retained behind the riffles. These concentrates are then further cleaned in the *batea*, or the gold is taken out with mercury. In material of moderate richness the gold is all caught behind the first riffle; in richer material, some of it may be found behind the second or third riffles. In skillful hands the machine effects an almost complete extraction of the gold, both fine and coarse. A machine of average size, worked by two men, has a capacity of 15 to 20 tons per day. The cemented gravels must be broken up before treatment by these methods, but this can often be accomplished by exposure to the sun and air, which effects a decomposition of the cementing material. Crushing by stamps or similar machinery is not economical, because it involves crushing the pebbles, which rarely contain appreciable assay values.

Llanos de Oro was recently the scene of an extravagant placer-mining operation in which a Los Angeles company under ill-advised management spent large sums of money on a stamp-mill and other equipment, entirely unsuited to the needs of the property. Some small interests operating in a conservative way are at present recovering gold economically from the cemented gravel in deep shafts near the Llanos de Oro. At the Chicharra placer, west of Llano station in the Magdalena district, attention has been given of late to the treatment of the loose gravel on a large scale by dry concentrators driven by gasoline power. A number of patented machines have been devised for this work, but many of them have been planned for treating crushed vein-matter rather than placer-gravel, and usually require the material to be reduced to 20 or 30 mesh. This is not practicable with the placer-
gravel of the region under discussion, for it carries much coarse gold, which will not stand screening finer than 1/3 in. mesh without loss of the precious metal.

A machine to be successful must therefore separate gold in nuggets up to 1/4 in. as well as gold so fine that it would float on water. The accompanying maps show the position of the principal placerfields in Altar. Others are known near the coast, and in the Magdalena, Aripe, and other districts, but those have not much commercial importance. That of La Ciénega, discovered in 1799, and long a source of gold extracted by the bolita, was made the scene of extensive operations from 1884 to 1894 by members of the Serna family, and others, who employed a large number of Indian laborers—10,000, it is said—to work the loose gravel with the Hungarian dry-washing machines. The total amount recovered was unquestionably great, although exact figures are lacking. There is a large amount of gold at present locked up in these placers which will, in time, be recovered by intelligent and economical methods of operation. But here, as elsewhere, it has been too often the case that the man employed to superintend the development and exploitation of a property has fortified himself with the dubious axiom which one so often hears from the representatives of mining companies that "a mine is no good that requires careful management." The chief difficulty in the working of these deposits is the variable distribution of gold. The rich bottom-layer of a corriente or channel may, in a depth or thickness of 8 to 12 in., carry as high as 2 to 21/2 oz. gold per ton. This gold-content is, however, not always continuous, and when the limit of a rich bed is reached, its continuation must be sought in the vicinity by diligent exploration. The barren intervals, if, however, rarely very great. Above the rich bottom-layer the gold-content is variable, and may fall to 50 c. per ton or lower. At this value the surface gravels may be worked profitably. There is, in my judgment, no question that, in the near future, these deposits will yield a good return to men of thorough technical training and experience in economical management.

The standard for the determination of silica in iron, adopted by the American Foundrymen's Association, is as follows: Weigh 1 gm. of the sample, add 30 c.c. HNO₃ (133 sp. gr.), then 5 c.c. H₂SO₄ (conc.). Evaporate on a hot plate until all fumes are driven off. Take up in water and boil until all ferrous sulphate is dissolved. Filter on an ashless filter, with or without suction-pump, using a cone. Wash once with hot water, once with HCl, and three or four times with hot water. Ignite, weigh, and evaporate with a few drops of sulphuric acid and 4 or 5 c.c. of hydrofluoric acid. Ignite slowly and weigh. Multiply the difference in weight by 0.4702, which equals the per cent of silica.

The exports of British-made mining machinery to South Africa during the last three years have been as follows: in 1905 the total value was £279,208; in 1906, £246,604; and in 1907, £250,035.

A PERUVIAN LEAD SMELTER.

Written for the Mining and Scientific Press by Lester W. Strauss.

The following notes, taken in June 1907, refer to the only smelter in Peru shipping argentiferous-lead bars. The smelter is at Vesubio, on the eastern side of the Cordillera Blanca of the Andes, in the department of Ancasch, at an altitude of 14,000 ft. above sea-level; the climate is somewhat rainy and snowy, but not excessively cold. It is distant from the coast about 135 miles by trail, which is covered in three days' riding; the road from Port Casma to Huáraz is fairly good, but from Huárez to Vesubio it is very rough. The highest point crossed is 15,000 ft. above sea-level and usually covered with snow and ice.

The ores treated are a mixture of galena, zincblende, pyrite, chalcopyrite, and tetrahedrite, in a quartz gangue, supplied by four mines distant 1/4 to 6 miles from the smelter. The ore is sorted at the mines. The assays vary from 5 to 36% lead; 23 to 110 oz. silver; a trace to 0.5% copper: 6 to 20% zinc, and 0.5 to 3% antimony. The ore is weighed as received, and is then screened through a suspended 8-mesh screen. The coarsest ore is ground in two arrastre mills, being a combination of a grindstone 4½ ft. diam., with 1⅔ ft. grinding face, a dragstone 3¼ ft. long, 1½ ft. by 1½ ft. in cross-section. These are driven from a vertical shaft direct connected to a horizontal water-wheel. The two mills grind about 61/2 tons per 24 hr. The ore contains from 2 to 3% moisture. Three men attend to the screening, while two feed the mills. The fine ore is shoveled into a 1½-ton charge-car, and trammed about 40 ft. to above the hopper of the reverberatory roasters. The two-hand reverberatories, when both are running, roast about 9 tons per 24 hr. The larger one only is usually at work, handling 6 tons per 24 hr. It is 57 ft. long and 10.8 ft. wide, being divided into 3 hearths and a fire-place (3 ft. wide). Wood is used as fuel. This is delivered for 30 c. per quintal, about 22 quintals being consumed each 24 hr. It takes 6 hours to work a charge of about 1½ tons. A little lime is mixed with the ore when dropped upon the hearth. The mass is gradually moved forward toward the fire-box, the men rabbling from both sides. Here it is allowed to sinter and agglomerate. Should this process be slow, some old lime, from the ceppling furnace, or iron-oxide ore con-
MINING AND SCIENTIFIC PRESS

September 12, 1908.

taining 20 to 25 oz. silver and 5% lead, is added. The finished product is drawn out onto the furnace floor, and the black compact mass is broken into small lumps. The ore, as charged to the reverberatory, contains about 20% sulphur, and the roasted ore about 7%. To attempt too close a desulfurization would mean an increase of lead and silver volatilization; some sulphur is necessary to take up the copper and form matte and prevent the gathering of inclusions in the lead-well. The silver and lead losses due to volatilization are probably 3 to 5% for the former, and 15 to 20% for the latter. The effect of roasting, in desulfurizing and volatilizing the lead, zinc, antimony, and silver, is to increase the lead and silver content of the ore smelted. The loss in weight due to roasting is about 25 to 30%. The process takes 12 men per 24 hours.

The roasted ore is carried up to the feed floor and dropped close to the furnace. The furnace is of circular type, being 1 metre in diameter at the zone of fusion, and 3.5 metres from the tuyeres to the charging floor. The tuyeres are 12 centimetres in diameter, the water-jackets 60 centimetres high, the remainder being brick-work made of local materials. Iron hoops placed 0.5 metre apart pass around the outside. The crucible is 20 centimetres deep and 1 metre in diameter. All the iron-work of the furnace is made in local iron, as well as the slag-pots, and accessories. The blast is delivered from a No. 3 Green blower, in a galvanized iron pipe, which distributes through a 20 by 22 centimetre air-box to the tuyeres. The air-pressure is about 12 oz. The top of the furnace is bricked over. A dust-flue leads off just above the feed floor to the flue from the reverberatories, being 80 centimetres square in cross-section. This connects with the stack, 8 metres high and 80 centimetres square in cross-section, which discharges 40 metres above the charging floor. The plant is operated by water-power. About 30 hp. are available, which are used for the Green blower and for a small dynamo furnishing light for the plant and quarters. The water-wheel is 4 metres high and 0.5 metre wide, made of the local wood ‘quinual.’

The furnace charges are usually made up on a basis of 225 lb. of roasted ore. The coal, iron-ore, and foul slag are conveniently close to the scales. The iron-ore, which is limonite, is obtained 6 miles from the smelter, and is delivered to the charging floor for 5.20 soles per ton (1 sol being worth a trifle less than 50c. gold). It contains 75 to 80% Fe₂O₃, 2.5 to 3% SiO₂, and assays 1 oz. silver. A clay deposit, distant 14 miles, supplies the necessary material for the bricks used in the reverberatory and blast-furnaces. Sand and kaolin are found close to the plant. The bricks for lining the lower exposed wall of the furnace are brought from the coast, and cost 40 centavos each. Little or no lime is used as flux in the furnace, there being sufficient in the gaugne combined with that used in the reverberatory. The limestone is brought about 5 miles at a cost of 5 soles per ton. Its composition is CaO, 51.5%; CO₂, 40.5%; Fe₂O₃, 3.4%; SiO₂, 4.5%. Coal of a semi-anthracite variety is mined about 25 miles from the smelter, and costs, delivered at the bins, 17 soles per ton. Its composition is, volatile matter, 12.3%; fixed carbon, 55.4%; ash, 2.3%. Its specific gravity is about 1.7, and it yields about 6400 calories (Berthier). The coal is compact and clean and has little or no sulphur. The average assay of the ore, prior to sorting, is about: lead, 16%, copper, 0.20%; zinc, 15%; antimony, 2%; sulphur, 20%; iron, 15%; silica, 20%; silver, 65 oz.; and gold, 0.09 oz. The foul slag forms an important part of the charge. A partial analysis shows, lead, 3.5%; copper, 0.3%; iron, 30.8%; silica, 33.3%; and silver, 12 ounces.

The following are the percentages and weights of fluxes charged on the basis of 225 lb. of roasted ore:

The coal charged is slightly less than 15% of the ore and flux, its weight being 75 lb. The number of charges smelted, per shift of 12 hr., varies with the running of the furnace, the minimum being 40 and the maximum 70, equivalent to 9 to 16 tons per 24 hr. The furnace smelts on an average 12 tons of roasted ore equal to 16 tons of raw ore; a total of about 27 tons of raw ore and flux being put through per 24 hours.

The slag is tapped 10 to 12 times per hour, passing from the furnace to a settler, and then to the slag-pots. Slag samples are taken as the slag flows from the settler to the pot. Daily assays are not made, the running of the furnace being judged by its physical condition, and by the specific gravity of the slag, which should be 3.8. If higher it is judged that there is too much iron, and is causing loss of lead in the slag. The slag is allowed to stand about 5 minutes in the pot and is then poured. The foul slag-shell is dumped on the ground to be broken and fed to the furnace. Sometimes the slag is poured into molds, 12 in. long and 6 in. square in cross-section, to be used as building brick. These are very strong and serviceable. The slag analysis is approximately, SiO₂, 30.9%; FeO, 42.3%; CaO, 7%; ZnO, 9%; Pb, 2.5%; Cu, 0.1%; and 6 oz. silver.

The furnace losses are silver 10 to 12%; lead, 20 to 25%; and copper 25%. These high losses are due to running with a ‘hot top,’ and to other poor furnace manipulations.

The flux-dust caught does not amount to much in weight. It assays from 26 to 30 oz. silver. Systematic sampling of the raw ore, roasted ore, foul-slag and slag are rarely attempted, only the bullion samples being regularly assayed, together with samples sent in from the mines. The slag issuing from the furnace falls on a bed of fine coal in the settler. The coal helps to reduce the lead, which is tapped once every 21 hr., yielding on an average 650 lb., or 8 bars.

The lead-well is tapped two or three times per shift, that is, 12 hours, depending on the quantity of lead in the crucible, which holds about 2000 lb., or 24 bars. It yields on an average 2700 lb., or 32 bars of lead per 24 hr. The molds are placed on a scale
near by and roughly weighed to 37 kg.; every seventh bar is set aside to be sampled. The average assay of 5072 bars shipped, is lead, 89% ; silver, 698 oz. (2.39%) ; gold, 0.95 oz.; copper, 3% ; and antimony, 3.5. The degree of concentration is about 12 tons of raw ore to 1 ton of bars. The lead-bars are trimmed up, each weighed, and the weight, in kilograms, and the lot-letter stamped on the top of the bar. Two to three bars can be loaded on a burro to be packed to the coast at Port Casma. The journey takes 6 to 8 days, and costs 2.70 soles per bar. There the bars are loaded on a coasting steamer for shipment to Europe. Formerly the lead-bars were compelled at the smelter, and only silver bullion was shipped. The furnace campaign is usually from 10 to 14 days per month, about 18 men being employed per 24 hr., including foremen, feeders, sealmen, tappers, slag-pot men, foul slag breakers, and roustabouts.

Native ‘cholo’ labor is fairly abundant. Wages vary from 40 centavos to 1 sol per day of 12 hours. Cost-keeping is not seriously practised, nor is information concerning costs willingly divulged. The following figures are based on a run of 16 tons of raw ore per day, figuring back from a lot of 800 tons of raw ore which produced 1596 lead bars. The silver is paid for on assay-value, less 4 centavos per ounce. Lead is paid for on assay-value, as likewise are the gold, antimony, and copper. All money values are in Peruvian currency. 10 soles or one pound sterling being equivalent to $4.85 U. S. currency. All tonnages are on the basis of 2000 pounds.

**SUMMARY.**

(16 tons smelted per 24 hours.)
- Administration, superintendent, and general costs: 8.00 soles
- Freight to Port Casma per bar: 2.70 soles
- Commission to agents at Port Casma per bar: 0.05 soles
- Pier charges and loading bars aboard steamer per 100 kg: 0.30 soles
- Charges for stamps, taxes, and watchman (from data for 10 lots): 0.65 soles
- Freight to Swansea: (rate at present time, June, 1905, is lower) per 2240 lb: 3.25 soles
- Freight from mines to smelter: 4.38 soles
- Crushing ore: 4.58 soles
- Roasting ore: 5.00 soles
- Smelting ore—Fluxes and fuel: 6.68 soles
- Labor, repairs, power, etc: 4.24 soles
- Administration, etc: 5.00 soles
- Freight on bars to Port Casma: 5.39 soles
- Port Casma shipping charges: 0.38 soles
- Freight to Europe: 2.39 soles
- Commissions and Insurance: 1.90 soles
- Refining charges: 1.75 soles
- Total: 32.69 soles

**The Prospector.**

This department makes a charge of 25 cents to subscribers not in arrears and $3 to non-subscribers for each determination.

L. L. B., San Diego county, Cal.: gold ore; quartz with limonite containing free gold; traces of sulphides remaining.

F. W., W. Vernon, Nev.: No. 1, rock now composed of silica, representing probably an original fissure-wall replaced by quartz; pyrite and secondary magnesian silicates occur; No. 2, tuff, partly decomposed; No. 3, metamorphie shale.

J. M., Dillon, Mont.: No. 1, fine-grained feldspar porphyry with disseminated pyrite; No. 2, pyrite (iron sulphide) in quartz; there are no evidences of platinum, but assays may show gold; No. 3, black sand, chiefly ilmenite (iron-titanium oxide); there was no platinum or gold in the sample; No. 4, pyrite in white sandstone; no platinum.

B. A. P., Grass Valley, Cal.: No. 1, fine-grained argite andesite; No. 2, fine-grained schist with pyrite seams; No. 3, decomposed schistose rock too badly altered to be identified; looks like altered modification of No. 4; contains some sulphide; No. 4, basic schist, probably a metamorphosed tuff; seamed with pyrite.
BLAST-FURNACE GASES IN SILVER-LEAD SMELTING.

By T. S. Austin.

Edited for the Mining and Scientific Press
By L. S. Austin.

Tests were begun in April 1893 at the Gran Fundición Nacional Mexicana, Monterey, Mexico, to see if practical data could be derived for use in controlling fuel-consumption. At first only the volume-ratio between the CO and the CO₂ in the furnace gases was determined. Later the absolute weight-ratios of these two gases were taken, but afterward the volume-ratio was computed to a weight-ratio, making no correction for temperature and pressure.

Analyses of Silver-Lead Blast-Furnace Gases.

**Series B.**

| May 16 | 38.3 | 9.5 | Furnace full, sample taken 2 ft. below surface (red heat) |
| & | 9.0 | 19.7 | Furnace full, sample taken at surface of charge |
| & | 19.2 | 18.2 | Sample taken 2½ ft. below surface |
| & | 19.8 | Sample taken at surface |
| & | 19.4 | 16.3 | Sample taken 3 ft. below surface |
| & | 17.6 | Sample taken at surface |
| & | 5.3 | 17.0 | Sample taken 6 ft. below surface |
| & | 7.2 | 21.8 | Sample taken at surface |
| June 5 | 6.9 | 20.5 | Sample taken 3½ ft. below surface (just red) |
| & | 4.6 | 23.6 | Sample taken at surface; speed high |

The first series, extending over two weeks, was tabulated so as to show, as closely as possible, the three important factors in furnace-working, namely, speed, reduction as given by lead-assay and fuel-consumption. Thus arranged, the hope was to find whether the ratios of CO to CO₂ would indicate a favorable or unfavorable state of affairs in any of these particulars. It would be a fair assumption that if the CO₂ was very high, compared to the CO, an economical use of the fuel was being obtained. If, at the same time, the lead in the slag was reasonably low, and the furnace-speed sufficiently rapid, the inference would be a low consumption of fuel with smelting-conditions very favorable. If, however, this low ratio CO/CO₂ should be accompanied by:

1. High speed, with a slag high in lead, the amount of fuel used would seem to be insufficient.
2. With high lead and low speed the amount of fuel would also be deemed insufficient.
3. With low lead and low speed the amount of fuel would be in excess of requirements for good work.

In another condition of the furnace, with the ratio of CO to CO₂ nearer unity, two cases might be presented:

1. If the slag were low in lead, and the speed rapid, the indications would be that too much fuel was being consumed.
2. If the slag were low, and the speed low, a like inference would be drawn.

Again, with the ratio of CO to CO₂ high, and with the slag also high, while the furnace was smelting at low speed, a solution of the difficulty could not be reached through adjustment of the amount of fuel used, but through changes of a mechanical nature, such as alteration in the fineness of the ore, or correction of error in charging, or possibly in re-evaluation of the slag-composition. This latter, however, cannot be considered a serious factor, as any metallurgist should be able to figure a charge and produce a slag suited to his ores.

Dividing our comparisons, then, into three heads, as regards the furnace, namely, speed, lead in the slag, and fuel consumption, the aim would be to correlate results with reference to a CO to CO₂ ratio.

Referring now to Series B of the table, the pairs of analyses taken, one at the surface and one at a distance below it, indicate that the CO has accomplished its duty in reduction. We may figure the velocity of the escaping gases through the charge at 5 ft. per second, both in the iron and in silver-lead blast-furnaces. Hence, a given portion of gas acts in the latter case but for a single second before it emerges at the top of the charge, in this brief period passing from about 600° C. (a low red heat) to a temperature of perhaps 120° C., and causing a change in the percentage of CO₂ and of CO, the former increasing at the expense of the latter. In the iron blast-furnaces the gases 30 ft. down, at the beginning of the zone of reduction, contain about 34.5% of CO and 65.5% of nitrogen. At the tunnel-head they may carry CO 24, CO₂ 16, and N 60%. Thus, in iron furnaces, the CO, on account of its greater concentration, is a more efficient reducer than in the case of silver-lead blast-furnace gases. These latter have, however, only to reduce the iron to the ferrous state.

**Arsine in the air** is usually detected by utilizing the reaction with HgCl₂ when a paper wetted with such solution is exposed to AsH₃. But various other gases which possibly might be present may give a yellow tint which simulates that produced by AsH₃. It has been noted that passing the air through a solution of CuCl₂ will remove those interfering substances, and that if the air so purified is then passed through a U tube containing a slip of paper moistened with HgCl₂, the paper will not show a yellow tint unless AsH₃ is present.
Air-Drill Lubrication.
Written for the Mining and Scientific Press
By THOS. J. BARROW.

I have become much impressed with the results obtained by an ingenious and effective combination of a valve and lubricating device for air-drills, manufactured by The Western Lubricating Valve Co., of Denver, Colorado, and believe that a wider acquaintance with it will lead to good results in several ways. Of all the machinery in use around a mine none is expected to render more service and none to receive as much abuse as rock-drilling machines. The superintendent of any large mine would not think of running his hoisting engine, or any piece of mechanism, without some efficient lubricator attached to it, yet he will send his rock-drills down into the mine to be used in the dirt and dust without any means of properly lubricating them, and then wonder why the repairs are so heavy and why the machines do not last longer.

The present practice of oiling rock-drills throughout the country is as crude as it was thirty years ago; that is, the miner goes down into the mine, at the beginning of the shift, and if he remembers it he pours a canful of oil into the machine to 'oil' it, but he more effectively oils the stope, because the oil is blown out of the machine with the first few strokes, and from then until noon the machine is supposed to be properly lubricated. At noon, if the miner thinks of it, he gives the machine another 'dose' of oil, and again oils the stope, and the machine is supposed to be oiled for the rest of the shift. Very often the miner forgets, or neglects, to oil the machine more than once a day, and I have worked in the mines beside men who did not oil their machines at all for more than one day in succession.

It can readily be seen that this process of 'oiling the stope,' rather than oiling the machine, has a greater effect on the ultimate results of mining operations than is apparent at first thought. In quartz-mining where the gold is free, and amalgamation is used to recover it, when the miner blows the oil through the machine onto the rock the oil adheres to and follows it to the stamp-mill, where it coats the coarse particles of gold and prevents their amalgamation. The result is, this gold is forever lost, because it is too coarse to be dissolved even where cyanidation is used in connection with amalgamation.

The Western lubricating valve admits of changing all this, and instead of the miner filling the machine with oil once a shift, he merely fills the oil-well of the valve, which is sufficient for more than a shift, and the oil is fed into the machine a drop at a time, and is consumed by the machine instead of being applied to the stope. This valve has other advantages over the common stop-cock, which is in common use throughout the country, in that it is always held in any position desired by the air-pressure flowing through the hollow turning-plug and against the stem, which prevents it from creeping except when desired by the machine-man. This feature effectively prevents the breaking of front-heads and side-rods, or other machine parts, when the steel 'shanks' on 'collaring' a hole, which is so common with the old-style stop-cock, which is continually opening and closing, due to the vibration of the machine while running. Another feature of the Western lubricating valve which is a decided improvement over the old-style stop-cock is its self-sealing or self-grinding properties. It is provided with a hollow turning-plug or key, through which the air flows against the stem, which holds the valve in its seat at all times, and thus every operation of turning on and off the air is essentially the same as grinding a new seat. The valve is provided with two swivel or 'knuckle' connections, one to the machine and another to the hose-connection, by means of which the wear on the threads in the air-chest of the machine becomes nil, and the hose is absolutely prevented from kinking.

I am informed by The Western Lubricating Valve Co. that these valves are being adopted by such concerns as the Homestake Mining Co., at Lead, South Dakota, which purchased 300 at one time; the Federal Lead Co., Flat River, Missouri, which has purchased 262 in three consecutive orders; the Liberty Bell Gold Mining Co., Telluride, Colorado; the Copper Queen Con., Mining Co., Bisbee, Ariz., which purchased 78 in two consecutive orders; and the North Star Mines, Grass Valley, California, which has 50 valves in use. Also as many as one hundred other mining companies have purchased these valves, which would seem to be proof of merit.

Light Storage-Battery Locomotive.

The Comstock Tunnel Co. has recently installed a 4-ton Jeffery storage-battery locomotive, shown in the accompanying cut, for use in handling the material as it is excavated in its tunnel-extension work. This locomotive is equipped with two 12-hp. series-wound, railway-type motors, and a 42-cell 16-kw.hr. battery, which in service will give an operating range of approximately 300-ton miles on a single charge when the tracks are approximately level. Owing to the great efficiency now attained in battery-locomotive construction, a very large demand has arisen for locomotives of this type for use in tunnel and reclamation work, and around smelters and large industrial plants where considerable quantities of materials are transported short dis-
stances. Where the hauls are not too long, and the tracks are approximately level, battery-locomotives weighing from 3½ to 7 tons are heavy enough for all ordinary purposes, and the cost of installation ranges from $1800 to $3400, depending upon the size. If the services of from two to six men, otherwise employed in pushing industrial cars from place to place, are thus dispensed with, locomotives in service show a net saving of from $600 to $2000 per year, after deducting all proper charges, including operating expenses, maintenance, depreciation, and interest on the investment. Where the number of laborers replaced does not exceed six, the services of a locomotive are usually required for only a very short time each day. If the work necessitates its being a constant use, a much larger force of men is replaced, and the saving effected is proportionately greater.

The economy in actual cost of operation is often secondary to the demand for rapid delivery.思密达 has increased expenditure for all demands from the promptness and facility with which the material is handled. The locomotive in question was supplied by the Jeffrey Manufacturing Co., of Columbus, Ohio, which builds locomotives suitable for every possible haulage-condition, including locomotives of the trolley-type, or combining the battery and trolley features, for use where all or only a portion of the track can be wired to advantage.

**Flint-Rim Sprocket-Wheels.**

The sprocket-wheel illustrated by the sectional view herewith has been developed by the Link-Belt Co., of Nicetown, Philadelphia, to meet the requirements imposed by the handling of abrasive materials, and by working conditions too severe for the employment of the regular type of cast-iron wheel. The teeth and rim exposed to the wearing-action of chain-contact are hardened to a considerable depth, and the surface is made smooth and uniform. This improvement in sprocket-wheels not only makes the wheel more durable, but actually prolongs the life of the chain by maintaining the original accuracy of fit between the links and the sprocket-teeth. The makers have coined and copyrighted a trade-mark, "Flint-Rim," for the new wheels, which are available in most of the active sizes of the 'Ewart' type of chains.

**Metallic Tubing.**

Flexible metallic tubing has been on the market for many years, and as time has passed has been brought to a high state of perfection as a conductor for oils, steam, gases, etc., under the highest of pressures. With moderate care, such as any hose should have, metal tubing will last for years, and, being constructed of steel or copper, they remain at full bore at all times, and for suction purposes will stand tons of external pressure. The U. S. Flexible Metallic Tubing Co. manufactures duplex tubings to withstand pressures as high as 3500 lb. per square inch. The single tubes, known as No. 5, with interlocking joint, are made of copper with a diameter of 3½ in., and will withstand a steam pressure of 250 to 500 lb. per square inch. The tubing may be handled with the same freedom as a rubber hose, insuring perfect safety to the handler. "Metal Hose" is considerably lighter in weight than any other form of flexible hose manufactured. It is more durable, more reliable, and in some instances more flexible, and therefore overcomes many difficulties contended with by the engineer. The demand for 'Metal Hose' is rapidly increasing. Sales from the factory during 1907 amounted to over 7,000,000 ft., which fact demonstrates its ever-increasing popularity. The manufacturers of 'Metal Hose' have their representatives established in San Francisco, southeast corner of Boyle and Mission streets, and in Los Angeles, 450 East Third street.

**Commercial Paragraphs.**

The Deister Concentrator Co., Fort Wayne, Ind., announces that it has recently sold four of its tables to the Cusquenas Copper Co., Ltd., of London, and also eight to the McKinniey-Durango-Savage Mines, Cobalt, Ontario.

Chalmers & Williams, of Chicago, have recently sold butt rapid cyanide filters to the Guanajuato Con. M. & M. Co., Guanajuato, Mexico; the Rosedale M. & M. Co., Magdalena, N. M.; and Makeever Bros., New York City, for El Tajo mine.

Unco. C. Moore & Co., San Francisco, has recently issued a handsomely printed and illustrated pamphlet describing the steam power-plant designed and built for the Pacific Light & Power Co., at Redondo, California. They will send this booklet to any address on application.

The Lane Slow-Speed Chilean Mill Co., of Los Angeles, announces that it has recently shipped Lane mills to the following firms: Emma L. M. & M. Co., Wadsworth, Nev.; Chvy Bros., New York City; Venable Bonding & Leasing Co., Boise, Idaho; Golden Surprise Mining Co., Butte, Mont.; Durango Mining Co., Los Alamos, Mexico.

The Bailie & Bradley Co. has recently taken over the agency of the Union gasoline, stationery, marine, and hoisting engines in Los Angeles, which includes the management of the salesroom at 210 N. Los Angeles St. This Company is also conducting a 'Machinery Exchange' at 943 N. Main St., where new and slightly used gasoline, steam, electric, irrigation, mining, contracting, and other machinery is bought, sold, and exchanged.

The Denver Engineering Works Co. has recently issued its Bulletin No. 1938, which proves to be a valuable work on modern stamp-mill methods and practices. This catalogue starts with a short description of the various steps in the process of stamp-milling, and while brief and to the point, it gives distinct explanations, sufficiently full to be intelligible and of value to the general reader. Then follow detailed descriptions of the various machines required in a stamp-mill, accompanied by well arranged photographs of the actual machines and parts. This description is followed by a complete specification for a 10-stamp mill, with general drawings, which should be a great help to the prospective purchaser or to anybody contemplating the installation of a stamp-mill. The last ten or twelve pages are given over to sectional drawings and photographs of a number of mills designed by this Company, giving a good idea of the several methods of construction. This bulletin is a valuable addition to stamp-mill literature.
EDITORIAL.

THE RECENT political changes in Turkey will open up for exploitation one of the richest mineral regions in the world, and will promote an enormous development of industry in the Orient. Railway building will become active throughout Asia Minor in the immediate future. These developments will not be without their effect in strengthening the financial situation, more especially in Germany, and improvement in one country benefits all.

PROFESSIONAL self-consciousness in the best sense is manifestly becoming keener among mining engineers, and the growing tendency toward a solidarity recognizing standards, limitations, and regulations mutually advantageous to practitioner and client, is finding expression in many quarters. We see the Mining and Metallurgical Society of America engaging in discussion over correct procedure, and across the Atlantic the London Mining Journal raises the question, 'Should Mining Engineers Advertise?' The fact is they do, and we think of some who are particularly zealous in seeking a conspicuous place where the limelight may illuminate them strongly. There are good ways and bad for making the world aware of one's presence. It is not always safe to trust to being advertised by loving friends. The question is largely one of good taste, but that is much, and certainly worthy the consideration of all who recognize that a first requirement of any profession, art, or form of labor, is dignity.

THE ELECTION of James Wickersham as delegate to Congress from Alaska is an event we are glad to chronicle, for he has emerged successfully from a campaign of vilification by sheer force of personal character. As judge at Nome, and later at Fairbanks, he brought respect to courts badly bespattered by the corruption of the boom-days, and his re-nomination as judge of the Third District, despite the failure of the Senate to confirm the appointment, proved the confidence of the President. The endorsement of Mr. Roosevelt is an honor to any public man, and it is so esteemed by the more intelligent portion of the public. By that pernicious fiction known as 'senatorial courtesy,' Mr. Nelson of Minnesota was able to prevent confirmation, but it is not too much to say that the action of the President in re-nominating the Judge was a better vindication than anything the Senate could do. In the recent election, the Judge, who resigned his office in order to run for delegate, had four competitors; the voting was decided mainly on local issues, of which territorial government and labor troubles were the most important. The candidate of the labor party made a good race; it is fortunate that he did no better.

For he is ill fitted for duty at Washington and his election as a representative of the labor-unions would
have made it impossible for him to represent the wider interests of Alaska. Of the five candidates, Judge Wickersham was the only man of national reputation, and the one best fitted by public service to be sent to Congress. We congratulate Alaska on the result, and we venture to express the hope that the new delegate will co-operate with the Governor in voicing the needs of the Territory in an effective manner. It is known that Governor Hoggatt and Judge Wickersham have quarreled, but both are men built on a broad gauge and of strong character. We hope that they will exhibit enough devotion to Alaska to sink personal differences and work unitarily in the public service of the Territory.

**COMMUNICATION** between the interior of Alaska and the outer world is maintained during the long winter by means of dog-teams. The carrying capacity is small, and the cost large. Hence the Government has been obliged to make contracts for a definite weight of mail to be delivered, and the result has been an enormous accumulation, especially of second-class mail, at the points of departure of the dog-teams. With the opening of steam service in the early summer this huge bulk of reading matter, which should have been available to help beguile the tedium of the winter night, is suddenly flung upon the mining camps, at the precise moment when everyone is too busy to read. In June of this year sixty-five tons of mail were dumped on the beach at Nome by the first steamer of the season! The Government has recognized the growing importance of Alaska, and the needs of its hardy pioneers, by arranging for an adequate over-land mail service in future. Weight remains the basis for contracts, but in doubled amount, and newspapers will go forward expeditiously throughout the coming winter.

**Tailing Wheels or Pumps?**

The tailing wheel was heralded ten years or more ago as a satisfactory solution of the vexatious problem of elevating sand in milling practice. It had apparently so many mechanical advantages over bucket elevators or pumps that its supremacy seemed secure. But fixedness is not a characteristic of engineering practice. In the course of development, methods which had been superseded are tried again to test their possibilities under new conditions. The centrifugal pump has once more become the hope of mine-managers on the Rand, and despite its higher consumption of power, the lower first-cost is claimed to overbalance the difference in operating expense. In recent experiments at the Rose Deep, Crown Deep, and other important mines, centrifugal pumps have been operating at an efficiency of from 40 to 45 per cent, and the cost of maintenance has been greatly reduced through the substitution of white-iron liners in place of manganese-steel, the difference in this instance being due to the possibility of producing the white-iron castings at local foundries. The opinion of engineers in favor of lifting sand by centrifugal pumps, and by that interesting spiral device known as the Frenier sand-pump, has been growing in America steadily in recent years. No prudent mill-designer would depend upon a tailing-wheel alone. He necessarily must parallel it with some other mechanism to serve in emergencies. The ruinous costs in milling are not usually those of steady operation, but the demurrage losses resulting from break-downs. The engineer must plan for mishaps as well as for smooth-running, hence the excessive cost of an elevator-plant in which a tailing-wheel is the leading feature. Mr. Walter L. Reid comes to the defense of the tailing-wheel, however, in a letter published elsewhere in this issue. His indictment against centrifugal pumps is severe, and is based upon two counts: excessive consumption of power, and higher cost of repairs. The disproportion, however, looks large, and it may be that the means of measuring power delivered were inadequate, since the horse-power stated for the tailing-wheel would yield the extraordinary efficiency of more than 85 per cent. The question of economy in lifting sand is of such great practical importance that we anticipate a lively discussion of the subject.

**Foreign Corporations in California.**

The general principle of comity constitutes the basis of nearly all legislation affecting the rights of corporations doing business outside of the country or state of their origin. Comity does not involve the extension of special privileges, although it is common for foreign corporations to seek and plead exemption from the laws of a host when they are found burdensome. It is certainly all that could be expected if the laws of a State concede equal rights with domestic corporations, which is the condition obtaining in California. A correspondent asks the authority which this implies to over-ride the provisions of a charter or articles of incorporation, harking back to that persistent plea of the foreigner for immunity which springs easily, like the proverbial 'hope eternal,' in the financial breast. The State is primarily concerned with the adjustment of relations between the legal persons within its borders. It has no jurisdiction outside those limits. But it admits no interference of another State in its administration of justice within that jurisdiction. Manifestly then the claim of a stock certificate that it represents a certain number of fully-paid shares in a corporation has no significance to the California court other than as it shows the fractional interest in a professed capitalization which any plaintiff or defendant may possess. And the shareholder, if coming bodily within the jurisdiction of the State, may sue or be sued. The State may not send its officers to hale foreign stockholders into court, but he whom it can reach it may adjudge, and if the case be one involving indebtedness of the company of which such person is a representative, he is liable for his share of that indebtedness *pro rata* with the amount of his holdings of stock, quite irrespective of what the stock may actually have cost him, or of the exemption from assessment or other liability which may be proclaimed in the articles of foreign incorporation. In California the foreign is placed upon the same footing as the domestic company, subject to like restrictions and obligations, and
given equal prerogatives. The home company is compelled to register with the Secretary of State as well as the foreigner; both are required to pay the same license fees; both are subject to the same penalties. These consist primarily in liability to a fine of $500 for failure to register within ninety days; next in the denial of the right to maintain or defend actions in the State courts, and finally in exemption from the benefit of the statute of limitations. These penalties, beginning with a fine for negligence, intended to compel compliance with the law on the assumption that the corporation had interests valuable enough to protect, terminate with a denial by the State of the legal existence of the recalcitrant organization. It is upon this theory that such a company is refused the right, not only to initiate, but even to defend an action. Being no longer known as a legal entity, it cannot be admitted into court as a defendant, the case goes by default, and judgment is rendered accordingly, which may be satisfied, first out of any remaining assets, and, in excess of these, by further action against any stockholders found within the jurisdiction of the State for their proportionate part of the unsatisfied judgment. This theory has been affirmed by the United States Federal Court (Diamond Gneiss Co. v. United States Gneiss Co., 103 Fed., 583), where the foreign corporation had brought action, and the defense, sustained by the decision, rested on the mere affirmation of incompetency of the plaintiff to appear as such because of failure to comply with the statutes of California. The Federal Courts have, in this and in other cases, distinctly held that only as an act of entity is a foreign corporation admitted to do business under the protection of the laws of another State.

A Mexican Wild-Cat.

We do not refer to Las Dos Estrellas Company in the remarks we are about to make. To those who may not have watched the miners' luminaries rise out of earth into the financial skies we will submit that the Dos Estrellas shines as a double star of exceeding brilliancy. The real Dos Estrellas mine is situated at Tlalpujahua, State of Michoacán, Mexico. It has a modest capitalization of $300,000, equivalent to only $150,000 United States currency. The production from the mine was so great that the shares, having a par value of $100, were eagerly purchased at $10,000, and French capitalists adjudged them a good investment even at that price. From the present undiminished output the judgment of the Frenchmen seems justified. It is manifestly because of the existence of this phemonal mine in Michoacán, with its world-wide fame, that another company has taken to itself the name 'Dos Estrellas Mines & Development Company,' under which borrowed lustre it may dazzle the public and attract the class that would buy lottery tickets if it could. The prospectus which has been issued promises such marvelous profits that it seems a pity to have sacrificed the opportunity of establishing a new name in glory. The company owns three mines, wherefore it might without vio-

lence have called itself the Tres Estrellas Mines & Development Company. There would have been no serious danger of confusion with the Dos Estrellas in that event, especially since the mines of the new company are in the State of Guerrero, hundreds of miles distant from the great Dos Estrellas of Tlalpujahua.

The new company is unique in several ways. There may be more unique features than one is able to discover without becoming a stockholder. It seems to be a Mexican concern in reality, though it exists under the laws of Arizona, with a nominal capital of $2,500,000 gold. The President is Gen. De La Paz Alvarez, the Vice President Juan Antiga, and the Secretary and Treasurer Licendro Maldonado. The promoters are Harvey A. Willis & Company of New York, who are literally giving away a sure thing for nothing. From their statement no funds are apparently needed for any purpose. The mines and works are leased to the Mutual Trust Company of Mexico for nine years. During the first five years the Trust Company is obliged to pay to stockholders of record dividends at the rate of two per cent monthly in addition to a royalty of fifteen per cent of the net value of the ore extracted. During the remaining four years of the lease the dividends, which the Trust Company agrees to pay, amount to forty per cent, plus five per cent of the net value of the ore. At the expiration of the lease the property, including all plant, is to be turned back to the holding company. In the face of this extraordinary contract whereby a trust company assumes all the risk and the owner is guaranteed a princely income without effort, expenditure, or anxiety, the promoters feel called upon to explain why the stock is offered for sale. The explanation is even more remarkable than the contract with the Mutual Trust Company. "Mexican bankers are desirous of building up prestige in the United States. They realize that the condition of the masses in their country can only be improved by the introduction of new capital, . . . This offering is made to build up an American following," since forsooth they have more sure things to donate later. This is exceedingly altruistic and beautiful, but it isn't business. The Mexican gentleman is looked upon as an astute financier. The American who thinks he can beat him at a bargain usually receives new light before the transaction is ended. In fact these worthy gentlemen who organize a corporation in Arizona instead of submitting to the stricter corporation law of Mexico, have evidently looked admiringly upon the sheep-shearing operations of Lawson & al., and have drawn the logical conclusion that a great deal of wealth exists in the United States which is easily detached from its possessors. They have manifestly observed that the more preposterous the lure, the more readily do the people answer with their golden offerings. There are a great many very foolish people in America, but it is painful to have the fact brought home so pointedly by foreigners. The Mexicans used to be too courteous to remind us of our weaknesses. Surely we must be Americanizing Mexico faster than anyone suspected.
MINING & SCIENTIFIC PRESS
September 19, 1908.

Personal.

W. E. THORNE was in San Francisco last week.

H. FOSTER BAIN is making an examination of the Illinois coalfields.

L. DE TOUVELLE was in San Francisco last week, and will soon return to Nicaragua.

E. Y. FOSELY is with the Black Mountain Mining Co., at Magdalena, Sonora, Mexico.

John RANDALL has moved his headquarters from Santa Fe, New Mexico, to Tollanda, Colorado.

A. A. HASMAN, of Toronto, has gone to Ontario and Quebec for examination and exploration work.

DODGERS WATERMAN is making an inspection of mining properties in Butte and Plumas counties, California.

H. F. LEFEBRE, of Reno, spent some time last week at the Butte plant at Virginia City, making cyanide investigations.

W. A. SCOTT, special traveling correspondent for the Mining and Scientific Press, is expected in San Francisco next week.

WALTER J. MORGAN has gone to La Yeca, Tepic, Mexico, to take charge of the cyanide plant of the Zapopan Mining Company.

WILBUR A. HENDRICKS, of Denver, has gone to New York. From there he goes to the State of Zacatecas, Mexico, on examination work.

WILLIAM S. MANN, general manager for the Boston & Oaxaca Mining Co., at Tlacolulco, Oaxaca, Mexico, has gone to Boston on business.

E. J. MOORE, Colorado manager for the Mining and Scientific Press, has returned to Denver after a three weeks' trip to the Pacific coast.

T. A. RICKARD will return to San Francisco the first of next week, after a three months' journey through Alaska and the Yukon Territory.

ROBERT K. PAINTER, of New York, has recently returned from a month's trip to Nevada, where he has been examining mines for Eastern capitalists.

HERBERT C. ENOS, of Johnson & Eno, mining engineers at Mexico City, has just returned from a three weeks' trip in the State of Hidalgo, Mexico.

JUAN FELIX BARTOLES, recently in the Parral district, is now in Colorado, and will return to London in two weeks. J. GORDON MACKAY expects to be in San Francisco in October.

RICHARD A. PARKER, of Denver, has recently returned from an inspection of the Hercules mine, at Silverton, Colorado, and has now gone to Chicago, Cleveland, and Boston.

GEORGE D. DODGE, has joined the staff of Spurr & Cox, Inc., as metallurgical engineer, and will be exclusively associated with that organization. Mr. Dodge's address for the present will be the Mexico City office of Spurr & Cox.

C. N. Gould, professor of geology at the State University, has been made Director of the Geological Survey of Oklahoma. The Geological Commission organized recently by electing Governor C. N. Manual president, State Superintendent E. D. Cameron secretary, and President A. Grant Evans of the University, executive officer. Field studies of the oilfields have already been taken up.

L. VOELKELT & Co., New York, give the following figures of German consumption of foreign copper for the months January to July, 1905:

Consumption of copper in 1904 59,747

The consumption during the same period in 1905 was 68,763 tons. Of the above quantity 87,573 tons were imported from the United States.

(By courtesy of Tripp & Co., 3rd Broad St., New York.)
General Mining News.

ARIZONA.

The work at the Superlair & Pittsburg is being pushed with great vigor, and according to late reports from the properties, good progress is being made. An official of the company states that during the past two weeks one of the biggest finds yet made was reported. A body of ore 40 ft. wide has been opened up on the 1300-ft. level of the Hoatson mine, on the Del Norte claim, and although no report of assays has been made public it is understood that the ore is of excellent grade and the outlook for a heavy tonnage is said to be good. The Superlair & Pittsburg properties are at present shipping about 100 cwt. of ore per week to the Calumet & Arizona smelter, at Douglas, and the shipments will be increased as soon as the smelter is enlarged.

GILA COUNTY.

(Special Correspondence).—At a distance of 25 to 40 miles from Globe in Fina and Gila counties on the opposite side of the Final Mtn. and along the Gila river is a new copper district about which comparatively little is known by the public. This new district has produced some copper during the last few years and promises exceptionally well for the future. The heavily mineralized zone extends from the Ray country on Mineral creek a distance of about 20 miles to the locality of Christmas, where the Saddle Mountain Mining Co. has done considerable work and pronounced ore bodies. The ore in the zone is not as at the other large company, the Hay Consolidated, with extensive holdings, together with a number of smaller companies, one of which, the Big Lead, was a year ago operating two small concentrating plants which have been closed since the panic. The copper deposit at Ray covers a large area, apparently limited in depth to a few hundred feet. It is a straight concentrating plant, and the copper being mainly in the form of calcite, the ore carrying an average of from 2 to 2.5% Active development was being done on a large scale until last fall, and since then churn-drilling has been done continually, proving more thoroughly the immense deposits. Next to the Ray country is the property of the Troy Manhattan Mining Co. Here some $500,000 has been expended, much of it in surfacing. There has been no work on the shafts sunk and one long adit has been driven. Along the extension of the same range of mountains, at a distance of about 10 miles from Troy, is a large group of claims owned by the London Arizona Copper Co. The property of this Company was extensively advertised in Los Angeles a little over a year ago. The advertisements ably emphasized the ore as one of the very best and of shallow development. The work has been done which has shown up an excellent carbonate ore. The claims are situated between the two localities where extensive cuttings have occurred. The ore, as far as known, is mainly in the limestone, which is, on top of a hard quartzite that is broken frequently by eruptive dikes and fingers of porphyry. Adjoining the London Arizona property on the east side are the Smoky and McHugh groups, containing small bodies of copper, and on the east the holdings of the Saddle Mountain Mining Co. At the latter more work has been done than any place in the district. On the surface are large quartz veins with considerable copper, and ore runs through the same. Although low grade, averaging about 3% copper, it is absolutely self fluxing, carrying about 20% excess base. A large tonnage can be worked in quarries, and underground the ground holds exceptionally well, practically no timbering being necessary. Eighteen months ago the Company had about 500 men on its payroll, a great number of whom were on railroad and other construction work; was smelting from 175 to 200 tons of ore per day, and actively pushing the mine development. The Company was putting its profits, together with additional money from the sale of stock, into development and construction work and new material. At present practically no work is being done. Through the entire district the properties are almost universally backed by good men with every intention of developing the section into a large and steady producer. At present, as well illustrated by the Ray Consolidated Co.'s deal with Hayden & Green & Co., the owners of the various properties are preparing to begin operations in the near future; and during the next few years this district will undoubtedly attract a great deal of attention.

Globe, September 12.

GRAHAM COUNTY.

The Southwestern Development & Improving Co. has not yet resumed operations on the Polaris property, although it is reported that funds will be forthcoming in the near future.—It is reported that the New England & Clifton plans the building of a concentrating plant at the Copper King mine, several miles above Clifton. The Company has a good mill-site on the banks of the Frisco river, with ample water-power available.—The New York Arizona Co., which is developing valuable gold claims in the district west of Morend, made a strike last week of four feet of ore which, it is claimed, will assay 70$ per ton. The find was made in the breast of the Lillian adit, 800 ft. from daylight.

MOHAVE COUNTY.

The Arizona-International Mining Co. is planning to start extensive operations at the old copper camp, 12 miles east of Yucca. Fred W. Morrison, of Los Angeles, who is president of the Company, was at the property recently making plans for raising money to purchase a complete equipment.

SANTA CRUZ COUNTY.

(Special Correspondence).—Work has commenced on the Cunningham group of claims in the Mowry district. A shaft has been sunk and the depth is about 120 ft. The shaft is now down about 40 ft. and a whim is being put up to take the place of the windlass. Five claims comprise the group.—Adjoining this is the Augusta group of claims, belonging to Ed. Burks, Fred Miller, and M. Marseller. They have a 90-ft. shaft on a vein of iron-stained decomposed porphyry. At the bottom of the shaft the vein is 6 ft. wide. From the shaft a drift has been run 50 ft. on the vein and some good ore taken out. The ore carries zinc, copper, gold, silver, and lead.—At the Four Metals mine, in this district, the adit has cut through the ore body in which it has been driven for the past three months. From the time of cutting into the orebody, until the narrow wall of granite was reached, the adit ran through 155 ft. of the orebody. During this time, the manager, has added 14 claims to the original group of 17, and a surveyor from Patagonia is now on the ground surveying for patent the entire group of 31 claims. Patagonia, September 12.

YATAPAI COUNTY.

The Tip Top Mining Co. is to lay 1100 ft. of new track in its adit and slope a large body of tungsten-ore which is now blocked out on that level. It is the intention to run the main shaft 600 ft. below the mouth of the adit. The Tip Top mine was one of the large silver producers of the country in the 70's. Work ceased on it when the price of silver fell below the dollar mark. Later the mine was partly dismantled by the removal of all the machinery adapted to the treatment of gold ore. This will necessitate the removal of the machinery and the reapplication of the mine can be treated on the ground.—The Black Chief Copper Co. has purchased a complete hoisting plant, and the development of the Uncle Sam group in the Black Hills district will be resumed. Sinking the main shaft was abandoned at a depth of 84 ft. on account of the great inflow of water. The group, comprising six claims, is developed and several shallow shafts and adits, ore being exposed in all openings which gave assays returning 25% in copper.—The Elta mine, on the eastern slope of the Black Hills range, 15 miles
south of Jerome, has been sold to an Eastern syndicate. A cloudburst recently carried away all the mining timbers, several hundred cords of firewood and ore buckets, besides wiping out of existence the dump at the mouth of the tunnel and shaft, which contained a large amount of ore of fair grade.—The mill of the Moneta Mines Co., 15 miles south of Kirkland, has recently been overhauled and put in shape. The ore is crushed in a Blake breaker and fed automatically to the 15-stamp mill, where it is crushed in cyanide solution. It is claimed that an extraction of 78% is obtained on the plates and a further saving in the cyanide plant brings the total up to 95%. E. S. Pettis is consulting engineer. Due, it is said, to internecine dissensions among the stockholders, the affairs of the Company and badly involved and bankruptcy proceeding were instituted last week. C. E. Bunker has been appointed receiver and all those acquainted with the property are satisfied that a few months operations will clear off all indebtedness.

YUMA COUNTY.

William Wilson and George W. Glowsner have sold their General Grant claim, in the Ellsworth district, 10 miles north of Victorburg, to John S. Wright, of St. Louis, for $55,000. An application for patent has been filed.

CALIFORNIA.

ELDORADO COUNTY.

The work of unwatering the Eureka mine, at Georgetown, was started last week. When the mine is again dry and the needed repairs have been made, extensive development will be undertaken.—Twenty men are employed at the Alpine mine, which is driven on to Nixon & Wingfield, of Goldfield, Nevada. The shaft is near the 400-ft. level and drifts are being driven along the vein both ways from the shaft. It is rumored that a milling plant will be built in the near future.—The Douglas Mining Co. has been incorporated to acquire and operate mining property and do a general mining business. T. H. Douglas is president. The Company owns valuable mining property in Eldorado county, and has recently completed the erection of a rotable mill in the vicinity of Bear creek, east of the main road from Placer ville to Georgetown on what is known as the Wagoner mine. Owing to failure of the water supply the mill can not be operated until the power plant, now under construction, is completed.

NEVADA COUNTY.

(Special Correspondence).—A good shoot of ore has been struck on the Creek vein in the Union Hill mine. The mill is running steadily on ore averaging $14 per ton.—A station is being cut at the 500-ft. level of the Norambagu and a 10-drill compressor will be installed.—The Brunswick mine has suspended operations and the underground machinery will be immediately taken out.—The adit at the Bear River mine has been practically completed. It is about 500 ft. long. Four veins have been opened up. The main vein is over nine feet wide. The Company is arranging to incorporate and work the mine extensively.—The North Star Mines Co. has purchased the Larimer quartz claim for $25,000. The claim adjoins the North Star group and contains seven water-right.—Arrangements are being made to install a hoist and pump at the Hill mine. Developments will be actively pushed.—Active developments have commenced at the Grant claims, near Granville. E. B. Smyth is superintendent.—Joseph Weishelm has made arrangements for the re-opening of the Gold Flat mine, and active work will commence within a short time. Good ore was exposed in the shaft when the mine was last worked.—Joseph Hales and John Sincuck are about to commence work on their claim, adjoining the Union Hill Mine. The 170-ft. lower adit will be driven farther to cut the main vein.

Grass Valley. September 14.

PLACER COUNTY.

The mill at the Lee mine has been shut down, due to scarcity of water.—The Bellevue is driving on a 2 ft. vein at the 400-ft. level. Forty tons taken from this level was run through the Malmberg mill last week and the cleaned-up amounted to 75 oz., valued at $1200.

SHERIDAN COUNTY.

Fred Bruckerman, of Poker Flat, has bonded his gravel claim in Stud Horse ravine to Los Angeles parties. The bond is said to be for two years and a half and the price $5000.—Sixty-five men are working at the Brandy City mine and head-dam. A large part of the flume has been completed. It is to be nine miles long, taking water from Little Canyon creek to Brandy City for hydraulicking. The improvements as contemplated by the Company will amount to $200,000 before the water is turned on.

TRITTY COUNTY.

The Chloride-Valley and Globe mines, near Pedrick, are to install an electric power-plant, and W. D. Pinkston, one of the owners, is now in San Francisco purchasing the machinery. A 10-stamp mill will be operated.—The strike made a few weeks ago in the West China adit is now showing up to be one of the richest finds made in Deadwood for many years. The ore has been opened up a distance of 75 ft., and the face of the drift shows 11 ft. of solid quartz.

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence).—The Buffalo M. & T. Co. is operating the Magna mine through the Doric adit, in carrying the stope to a height of 190 ft. have exposed a streak of smelting ore that is from 1 to 4 ft. wide. A shipment of carloads of carlina will be made last week. Several hundred tons of waste rock was included, settlement was effected at the rate of $45 net per ton. It has been decided to henceforth mill the product in two classes, as assay tests show the first grade to be worth $185 per ton in gold, silver, lead, and copper. A force of 30 men is now employed. Within the near future the adit is to be driven forward, as a number of veins are controlled lying ahead of the present workings. L. J. Larsen is superintendent. The Raymond adit, on Griffith Mtn., this week intersected the Valentine vein at a distance of 950 ft. from the portal. A number of small streaks of mineral are in evidence, but the full extent of the discovery will not be ascertained until the hanging wall is reached. J. Raymond is manager.—A good showing is resulting from the development of the Shirley Brown Mtn. In extending the east drift from the 500-ft. level, a streak of ore is exposed for a distance of 60 ft. that is from 4 to 6 in. wide, the value of which is 975 oz. silver per ton. Stopping has been started, and B. J. Marton, the manager, will start regular shipments in a few weeks. It is intended to continue the drift for 75 ft. A good force of men is being employed in repairing the old workings, to permit of the extraction of the bodies of medium and low-grade ore that were left during the early history of operations, when none of the product was handled that carried less than $10 per ton. A concentration of small capacity will be erected during the winter months.—The assay and sampling plant at the Capital mines has been completed and now all concentrate and smelting ore are being tested previous to loading to the local smelter. The 10-stamp mill will permit of all ore carrying more than $25 per ton being kept separate from the milling grade. F. Graham has been made manager. The east and west Asta drifts have been run for 900 ft., and the orebody is exposed for the entire distance. Eight raise are being made and for 150 ft. the stope has been proved.—A meeting of the stockholders of the Two American Sisters M. M. P. & E. Co. was held in Georgetown this week, at which time the sale authorized some weeks ago by the board of directors was ratified. S. Peacock and J. A. Mears, the purchasers, are now employing a force of 40 men at the mine, and extensive development is in progress. The consideration was $200,000, and it is now understood that the electric plant two miles below Georgetown is to be purchased, for $100,000. The plant has a capacity of 550 hp., with an excess guarantee of 25% during high-water period. Power is being sold throughout the vicinity of Columbian Mtn. Work in the mine is being centred on the 160 and 275-ft. levels of the
Headlight shaft, and driving and stoping are in progress upon fine bodies of ore. The 59-ton concentrating plant has been thoroughly overhauled, and since starting the machinery two weeks ago a high saving has been effected.

The Marshall-Russell adit, on Miller Min., has been advanced 2000 ft. According to surveys, the Neorf vein will be reached at any time. This vein was a good producer from shaft workings, the estimated production being 75,000. Progress on the main adit is being made at the average rate of 6 ft. per day, and it is understood that funds have been provided for the continuation of work for a period of six years.—Butler & Co., leasing on the Wheeling vein through the Toby adit, are sending out semi-monthly shipments of $50 ore. A small streak of telluride of silver is running through the main streak, which brings returns of from $1000 to $7000 per ton in gold, silver, and lead.—Miller & Co., leasing on the same property, have sold their privileges to the Waldorf Metals Co., which recently secured a 16-year lease on a large part of the holdings of the Waldorf M. & M. Co. Work is under way and the force is being added to from time to time.—Report is current that a deal will shortly be closed whereby the Santiago mine, in East Argentine, will be transferred to a syndicate of Eastern men, the consideration being said to be $500,000. This property makes the finest showing of any to be found in that locality. Leases have been notified that they need not expect an extension of their privileges within the next 18 months, and the hope is being brought to bear for the extraction of as heavy tonnage as possible.—A new company is being organized to develop the Pliz group of claims, and it is understood that a working fund of $20,000 has been provided. The adit is to be driven forward. G. S. Redd, of Denver, is manager.

Georgetown, September 12.

LAKE COUNTY.

An important strike was made during the week on the Big Six, at Leadville, at the 755-ft. level. At this point the seams are running an incline shaft toward the Penn territory, and a few days ago struck a body of lead-silver ore that runs high in the white metal. The whole breast of the incline is in ore and some of the assays taken from the orebody run as high as 325 oz. silver and a good percentage of lead.—The Leadville-Belvidere adit in the Horshoe mining district is now on a paying basis, and while the work of driving the bore continues, the property is producing regularly a fair tonnage of good ore, which is currently being shipped. The property is estimated to be 150,000 tons of ore, and this company hope to have it one of the heaviest producers in the district in the course of time.—An increase of over 3000 tons over July is figured by the railroads as representing the output of the Leadville district for August. It is admitted, however, that this increase, even small as it is, does not represent the substantial growth of activity. Most of it was accomplished by work being done on the various dumps in California gulch and on Fryer hill. However, much work is going on which is not represented by tonnage figures. This includes the new tunnel proposition and development work on many shafts in the district. The Dinerco and other properties west of the river, are employing many men, but not shipping anything, as they do not expect to reach shipping material for quite a while.

OURAY COUNTY.

A small force of men is now at work on the Sutton group, on Mt. Hayden, excavating for buildings and driving the cross-cut drift to the Denver lead. It is probable that an electrical equipment will be installed instead of air-plant.—It is probable that work will soon be started on the Blowout adit of the Ouray Con. Mines Co. The assessment work has not been done for this year, and it is the plan of the Company to continue work when it is once started.—The manager of the Neosho has gone East, where he will confer with the officers of his Company concerning the installation of a large plant of machinery on the Neosho. The work is going on with hand-drills and it is likely that while East an order will be placed for a large plant.

SAN JUAN COUNTY.

The August shipments from Silverton amounted to 2900 tons of concentrate and 1075 tons of crude ore. The Gold King will be running again this month and will swell the shipments for September.—It is reported that the Ross Mining Co. will make another test run on ore from the Champion mine at the Conover mill, before proceeding with the erection of its own plant.—The Bagley adit, at Animas Forks, cut the Red Cloud vein last week at $5000 ft. from the portal. The vein at this point is 12 ft. wide, but does not contain mineral in payable quantities. Driving to the east has now been started to reach the well known orebodies in that direction.

IDAHO.

SHOSHONE COUNTY.

(Special Correspondence).—A new water-driven air-compressor is to be installed at the property of the Aeolian Copper Co. and the ground for the building is now being graded. The compressor will have a capacity of two drills. A long flume is also being constructed by the Company to connect with the waters of Deadman gulch. In addition, a large amount of money is being expended on new equipment. The property is being financed by a syndicate of French capitalists.—A six months’ lease of the property of the Idora Mining Co. has been given to F. M. Mark, of the M. G. and W. D. Robertson group. The lease is being brought to bear for the extraction of as heavy tonnage as possible.—A new company is being organized to develop the Pils group of claims, and it is understood that a working fund of $20,000 has been provided. The adit is to be driven forward. G. S. Redd, of Denver, is manager.

Georgetown, September 12.

LAKE COUNTY.

An important strike was made during the week on the Big Six, at Leadville, at the 755-ft. level. At this point the seams are running an incline shaft toward the Penn territory, and a few days ago struck a body of lead-silver ore that runs high in the white metal. The whole breast of the incline is in ore and some of the assays taken from the orebody run as high as 325 oz. silver and a good percentage of lead.—The Leadville-Belvidere adit in the Horshoe mining district is now on a paying basis, and while the work of driving the bore continues, the property is producing regularly a fair tonnage of good ore, which is currently being shipped. The property is estimated to be 150,000 tons of ore, and this company hope to have it one of the heaviest producers in the district in the course of time.—An increase of over 3000 tons over July is figured by the railroads as representing the output of the Leadville district for August. It is admitted, however, that this increase, even small as it is, does not represent the substantial growth of activity. Most of it was accomplished by work being done on the various dumps in California gulch and on Fryer hill. However, much work is going on which is not represented by tonnage figures. This includes the new tunnel proposition and development work on many shafts in the district. The Dinerco and other properties west of the river, are employing many men, but not shipping anything, as they do not expect to reach shipping material for quite a while.

OURAY COUNTY.

A small force of men is now at work on the Sutton group, on Mt. Hayden, excavating for buildings and driving the cross-cut drift to the Denver lead. It is probable that an electrical equipment will be installed instead of air-plant.—It is probable that work will soon be started on the Blowout adit of the Ouray Con. Mines Co. The assessment work has not been done for this year, and it is the plan of the Company to continue work when it is once started.—The manager of the Neosho has gone East, where he will confer with the officers of his Company concerning the installation of a large plant of machinery on the Neosho. The work is going on with hand-drills and it is likely that while East an order will be placed for a large plant.

The work is going on with hand-drills and it is likely that while East an order will be placed for a large plant.
the rate of six feet per day. This new Company is the recent consolidation of the Velvet, St. Ives, Gold Horn, and Putlatch groups.—The Baby Florence lease on the Florence Goldfield has been granted an extension of 30 days, carrying it to February 6 at midnight, and the Gem Florence on the same property received a six months' extension.—L. L. Mushett and associates, who own a one-half interest in the Mushett lease on the Miss Jessie claim of the Laguna, have purchased the remaining interest from the Goldfield Gold Mountain Mining Co. A heavier plant of machinery has recently been installed and a large production is promised for the future.—George B. McClellan has taken a lease on the upper vein of the Nevada Cottonwood mines Co., at Stimler. He is putting up machinery and cross-cutting at 100 ft. Rich ore was found in sinking the shaft, two feet assaying as high as $116. Two other leases have been let on the property.—The mines of Goldfield promise an increase in tonnage, and September 12 a total of 2552 tons, estimated to be worth $170,500. During the same period the Tonopah mines produced 6049 tons of an estimated value of $160,890.

HUMBOLDT COUNTY.
The Seven Troughs Columbine Mining & Milling Co., owning the Key West and Colorado claims, in the Seven Troughs district, is arranging to start work upon its property soon. Good surface assays have been obtained, and its proximity to other producing claims makes the prospects bright.—W. R. English, of the English-George-Preston lease, near Maruma in the Seven Troughs district, will place a hoist on the lease by the end of October. The plant for the new vertical shaft of the Seven Troughs Kindergarten Mining Co., arrived in Lovelock last week, and will be installed at the shaft at once. The engine is 25 hp. and the plant will constitute one of the best mine equipments in the Seven Troughs district, and will be amply fitted in every way to handle the large ore tonnage for the mill to come from below the 390 ft. level. The Kindergarten shaft, which was started less than six weeks ago, has reached the 110-ft. point. The work of sinking has been pushed with great speed during the last 10 days, during which time two shifts have been working.—With its newly completed ore-bins filled with ore, the Reagan lease on the Maruma Hills estate began the second mill-run at the Maruma Hills mill last week. Three hundred tons will be treated.

LINCOLN COUNTY.
Alunite, a new camp 23 miles southeast of Las Vegas, has been attracting attention during the last month. The Hill Syndicate, of New York, has been interested in that locality for some time, and, in fact, it was Robert T. Hill, the head of that concern, who first discovered the presence of alunite there, and first realized its significance. Alunite has usually been found, when present in considerable quantity, associated with rich gold ores, this relation having been especially noteworthy at Godfield, so that an alunite-type of gold ore has become recognized by economic geologists. It is said by those who have visited the new district that the formations at Alunite duplicate those at Godfield, and that the prospects are better. Many shafts are being sunk and the rush to the new camp is on.

—the Pioche Water Co., the stock of which is owned jointly by the Ohio-Kentucky and Nevada Utah Mines & Smelters corporation, has decided to make some needed improvements in its water system at Pioche. In the town the old mains are to be torn up and replaced with new. But the first work to be done will be that of installing two large reservoirs capable of storing 200,000 gal. of water. Ernest L. Godbe is manager of the water company and has been instructed to go ahead with the proposed improvements.—The Searchlight Consolidated owns per capita stocks at the Oregon last week. H. L. Norman is in charge of the work. The main shaft is now being unwatered, preparatory to continuing sinking.—The Searchlight-Parallel has leased the Cyrus Noble mill and is treating the dumps at the Elvira and the Birdie shafts. This work is only preparatory to starting underground development.

NYE COUNTY.
The Edelweiss Co., operating on the east slope of Ladd Mtn., is grading for the installation of a whim. The shaft is now down 110 ft., and sinking will be resumed when the whim is installed.—The Panion-Faulkner mining property, at Manhattan, has been sold to a group of San Francisco men, represented by W. J. Roderick, of Manhattan. The new owners contract to continue the shaft down 65 ft., to the 200-ft. point.—After a lapse of 20 years, work has been resumed on the old Belmont property, near Manhattan. James Shes, Dick Roberts, and Eph Putman have secured a lease, and will put in a 25-hp. hoist. The incline-shaft is 1190 ft., giving about 690 ft. vertical depth. The leases will unwater the shaft and begin taking out ore.

WHITE PINE COUNTY.
The Alpha shaft of the Gioux Consolidated has reached the 1200-ft. point, and the work of cutting a large station has been begun. The winze from the 1000-ft. level is down 50 ft. below it, and is still in the big body of copper ore that runs 11% copper, and is rapidly being deepened with as large a force as can be worked to advantage.—The St. Lawrence Mining Co., whose property is in the old Shoshone district about 50 miles southeast of Ely, will soon start construction on a 100-ton mill in Lincoln canyon. The foundations will be put in this fall and actual construction of the mill and an aerial tramway will be rushed next spring. The ore is said to contain 60% lead and some silver.

UTAH.
SALT LAKE COUNTY.
The Little Eddy Mining Co. has closed a deal with the Utah Copper Co., whereby the latter company has possession of certain surface rights on the Little Eddy group of claims in Bingham for a consideration of $12,500. With the rights secured from the Puritan Gold & Copper Co., which owns a property adjoining, the Utah Copper has secured about 25 acres which is to be used as a dumping place for the overburden removed from the copper-bearing porphyries of Bingham. It is also to be utilized for railroad tracks, the right of way of the proposed Bingham & Garfield railroad
crossing over the ground just acquired.—A body of rich carbonate ore has been cut in the High Line adit of the Tom Moore property, which is said to run as high as 68.9% lead and 80c. in gold. The Tom Moore is owned by Mr. and Mrs. T. M. Surlough, of Salt Lake, and the estate comprises approximately a mile square of ground. The owners have been developing it as they could, without incorporating, for a number of years, and they have opened fairly good showings in several places.

SUMMIT COUNTY.

An assessment of one cent per share has been levied on the stock of the Copper Apex Co., delinquent on September 21. Work has been resumed in driving the adit and development will be pushed.—The Western Monitor is advertising for bids for sinking its shaft 100 ft. deeper. Preparations are being made to carry on work all winter, and the buildings have been repaired and a storage water-tank put in. At the meeting of the stockholders of the American Flag Co. held at the mine last week the present board of directors was re-elected and routine business transacted. The Company's affairs were found to be in splendid shape and the reports on the condition of the mine were all most encouraging.—The recently organized Park City Mining & Power Co., of which S. W. Pllatt is president and W. H. Pauli, secretary, now has a force of five men employed at its property in Big Cottonwood. Besides owning a tract of the most favorably situated ground in the district, the Company has secured the State water-rights on the stream there, and the water is used as motive power at the mine. With the aid of power-drills excellent progress is being made in the adit.

CANADA.

BRITISH COLUMBIA.

(Special Correspondence.)—Coke is beginning to come into this district after a shortage for several weeks. No fuel is being received from Fernie, but shipments are expected from that point in about ten days. The Granby Co. has received several thousand tons of stock coke from Michel, and again has seven furnaces glowing at the smelter. The weekly shipments from the Phoenix mines to Gran Torks have lately fallen as low as 13,700 tons, caused by the coke shortage, which resulted in the Granby mines closing down on Saturday and Sunday of the last few weeks. Ore shipments, however, will soon be increased to 500 tons per seven furnaces when the situation is normal. The dismantled furnace is being lengthened 4 ft. 4 in., which will make its length when finished 22 ft. This work will take three weeks. Each of the furnaces will be altered in this manner, which will increase the capacity of the smelter from 3500 to 4500 tons per day.—The B. C. Copper Co. was but little affected by the Fernie disaster as this Company obtained coke from Coleman, Alberta; hence, it has been able to maintain steady operation.—Mining at the Brooklyn and Rawhide mines of the Dominion Copper Co. has been resumed after a shut down of several weeks. The large furnace at the Boundary Falls smelter will be blown in within the next few days.—The Consolidated M. & S. Co. of Canada has started shipping from the Snowshoe mine to the Trail smelter. Although unprofitable last year, the Company has learned that the ore is rich in copper. Only enough ore for smelting purposes will be shipped from the Snowshoe while copper remains at its present low figure. Active development work is now being carried on at the Snowshoe and War Eagle holdings of the Consolidated at Phoenix, and ore will be hauled out preparatory to heavy shipments as soon as the market will warrant it.—Local stockholders in the Granby Co. were disappointed to learn that the directors of the Granby, in convention at Boston, had taken no action on the question of a quarterly dividend. It is understood that the Company is making some profit on its operation, but it is presumed that the directors in passing the question of a division of profits are acting in the best interests of the concern, and the present unsettled condition of financial affairs somewhat reconciles the situation.—Charles Cansell, Dominion Geologist, has returned from a visit to the Similkameen country. Topographical work is now being carried on in the Upper Tulameen platinum-bearing zone. This district is rich in mineral and will come rapidly to the front as soon as railways are built through it.—The Centre Star, Le Roi, and Le Roi No. 2, Ltd., of Rossland, are keeping up to their regular shipping standard and the ore at depth in these mines is coming in more plentiful as development proceeds.

The following table shows the different mines that shipped lead ore to the Trail smelter during the month of July and is doubly interesting from the fact that it shows approximately what these different mines are shipping to Trail each month and the lead content of their ores:

ROSSLAND, September 12.

YUKON TERRITORY.

(Special Correspondence.)—During the past three years there has been a great deal of agitation and no end of endeavor on the part of the people of this Territory to have several large concessions cancelled, the chief among these being the Anderson, on the lower end of Hunger creek, covering about three miles of the creek bed and hill sides; and the Bronson & Ray, on the lower end of Bosanca creek. The fight was maintained on the concession grounds on the ground that the owners had not lived up to the requirements of their lease, which made it compulsory for them to install either a hydraulic plant, or some other equally efficient method. Neither of these concessions have installed the kind of plant that the people of this camp think cover the requirements of their lease, and it was thought that it had been clearly proven that the contention of the people was correct; however, the matter has come before the Supreme Court of Canada affirning the title of the concession owners, and so far as can be seen now the case is at an end. The public naturally feels a good deal of satisfaction at its defeat, nevertheless it has had the effect of convincing a great many people that whatever the Canadian Government gives, is not to be lightly taken away, and in this way has done a lot of good, by showing that after all there is security of title in the Yukon, a condition which unfortunately has often been disputed. It is generally understood that both of these concessions, which are most valuable, have become part of the immense holdings of the Yukon Gold Co., who have already a 7-t. Bucyrus dredge installed and at work on the Anderson concession, and are now preparing to carry on hydraulicing on a very large scale on the Bronson & Ray next season.

Dawson, August 30.
Special Correspondence.

NEW YORK.

In talking with George W. Bryant, of Guanajuato, with reference to the feeling there regarding the Mexican situation, he stated that the proposed mining legislation has caused little disquiet, as everyone was satisfied that it would not militate against the employees' profit sharing. The objection to the law lies in the fact that the Mexican Corporation Law, which everyone wishing to obtain properties under the new law would have to adhere to, is loosely drawn and contains several objectionable provisions. A clause which would prove troublesome provides that 10% of the capital stock must be paid in before incorporation. This would tend to prevent large amounts of capital from going into mines far too small for efficient operation. But the Mexican Government, with its usual fairness, will undoubtedly listen to the protests the proposed laws have aroused, and foreigners may rely on receiving generous treatment combined with such regulation as is necessary to exclude only the undesirable elements. Mr. Bryant reports the Pinguisco mine to have made a net profit in August of $189,000, U. S. currency, from 640 tons of ore, and the Pegegrina a profit of $50,000 in the same period.

The annual report of the American Smelting & Refining Co. has caused a good deal of comment. The list of stockholders of record on August 1 contains four members of the Guggenheim family, with a total of $700 shares, while Daniel Guggenheim has only one share of preferred stock. H. H. Rogers and the Rockefeller interests are conspicuous by their absence, but the largest individual shareholder is Theodore Freeman, with 20,900 shares, who is associated with B. L. Smythe & Co., a firm which does a good deal of business for the Standard Oil interests. As the stock is evidently held in the names of dummies, it is impossible to tell just how matters stand. It is said that John D. Rockefeller purchased large blocks of the stock during the panic, and has unloaded at a big profit since; and on August 7 that the Guggenheims had regained control by the purchase of 50,000 shares at $88 per share. As the president of the Standard Oil Co. takes little speculative interest in the market, it is possible that the frenzied frenzy in 'Smelters' which accompanied the advertising campaign from Boston made it possible to buy his close holdings, even at the high prices. Anyhow, Smelters has lost its reputation as a conservative investment on account of the methods used to exploit it in the market. An interesting question is whether the Guggenheims got out, and if so, if Lawson got out with them. While a house that acted as its agent in the Yukon campaign had large holdings on August 1, the stock advanced from 90 to 107 since then, and it is believed he unloaded upon the long suffering public which is ever ready to 'hold the bar.'

A certain amount of friction between the Guggenheims and the old Smelters crowd has been revealed, and it is possible that the control may be wrested from the present management. President Daniel Guggenheim in his report said: "After deducting on account of betterments and ordinary repairs the sum of $233,129, the net earnings for the past year have amounted to $7,632,286. There was deducted from the net earnings of the preceding year $540,119 on account of employees' profit-sharing fund, and $1,054,966 on account of new construction and improvements, or a total of $1,595,416, whereas during the past year there has been used on account of employees' profit-sharing fund, and the amount deducted for improvements and new construction and improvements have amounted to $622,096. The net amount applicable to the payment of dividends shows a reduction, as compared with the preceding year, of $2,903,862. Together with most commercial enterprises in this country, our company has suffered as to earnings. The simultaneous and sudden decline in the value of lead, silver, and copper, together with no proportionate decline in the expenses of operating mines, notably in freight, supplies, and labor, made it unprofitable for many of the mines under contract to the company to continue their usual output of production. This has the inevitable and inevitable result of bringing about the reduction as shown. The large surplus already accumulated, however, was not impaired, and now amounts to a total of $13,405,218.

The directors thought it best to reduce the dividend on the common stock for the last quarter of the fiscal year to 5%, thus bringing down the dividend to the net profit of the year, even after charging off against profit and loss the entire amount expended during the year for improvements and new construction. There has been completed and added to the property of the company during the past year a lead and copper smelting plant at Chihuahua, Mexico, which commenced operation in July, 1908. The entire cost of the construction of this plant has been charged to profit and loss, as has been the usual custom of the company in connection with new construction for the past five years. There is a marked improvement, at the present writing, in the market-value of copper and lead. The directors feel warranted, therefore, in expecting that the net earnings of the Securities Company for the coming year will not make necessary any further encroachments upon the surplus, and it is now probable that dividends will be called upon to make any payments under its guarantee of dividends on Securities B preferred stock.

FAIRBANKS, ALASKA.

Stampede up Innoko River.—Profitable Developments.—Costs of Supplies.—Discoveries in Hot Springs District.—Construction of Important Ditch-line.—Conditions in Fairbanks District.—Rich Drift Mines.

The latest news from Innoko is brought by Dr. W. H. Brown, of Chena. There was a big stampede up the Innoko river this summer, but most of the prospectors are returning disappointed. Nevertheless, the outlook is not wholly unfavorable. Seven or eight claims are in pay gravel, and from 10 to 15 claims promise to be productive. One of the most successful is F. H. Coulme, an experienced French-Canadian prospector, who has been in Alaska since 1889, and who went up the Innoko in 1908. He staked No. 4 bench claim on French hill above Gaines creek, and other claims on Glacier and Spaulding creeks; No. 4 bench claim has yielded $20,000, and he sold his one-third interest for $800. He has gone to his home at Stoop, and has left $1,010 in his 'poke.' Others will clean up good stakes, but nothing very big. Operations have been hindered by the high prices of supplies; for instance, flour has been selling for 35 cents per pound and bacon at 75c. per lb. The country is accessible with difficulty. Everything has to be brought in small boats for 175 miles above the limit of steamboat navigation; the streams are tortuous, and poling has to be aided by 'lining.' As much as $15 per 100 lb. was paid for bringing freight 15 miles up one of the creeks. There is some water for mining on Gaines and Ophir creeks, and two good rains helped, so that about $150,000 will be taken out this season. The ground is frozen, but it is only from 3 to 4 ft. to bedrock in some places, and the maximum depth is 30 ft. There are 400 men in the region this winter, but they will be scattered over an area fully 150 miles square.

Another important stampede this season was that to Sullivan creek, in the Hot Springs district, southwest from Rampart. Sullivan creek is on the south slope of Moose Mtn.; pay gravel has also been found on Tulty Gulch. The ground is said to yield from $2 to $4 per square foot for bedrock, about 2½ ft. of wash and 1½ ft. of bedrock being extracted. Rich gravel has been struck at 54 and 58 ft. below the surface, and the channel is estimated to be fully 400 ft. wide. One shaft struck bedrock at 105 ft., but on several claims open-cut work is being done on ground only 9 to 10 ft. deep. There is plenty of water for small opera-
tions, and the men returning from the Innoko are coming to Sullivan creek every day.
In the other and older parts of the Hot Springs district, the lack of water has almost put a stop to mining. On Thanksgiving, Glenn, Eureka, and Pioneer creeks the shortage of water will result in a marked shrinkage of gold-production this season. Even copious rain at the end of the summer, now near at hand, could not rebalance the deficit. Lack of water has led to the making of surveys for a ditch line of New Hamshower, C. M. Loveridge, of San Francisco, are making a survey looking to bringing the water of Hootlilama creek to Thanksgiving creek and the other diggings now controlled by Frank G. Manley. This survey includes the construction of a tunnel through a dividing ridge, and as the tunnel must be about a mile long, the cost will be serious, having regard to the quantity of water available, namely, about 1560 miner's inches; but owing to the character of the gravel-deposits even this quantity of water will permit a large production of gold. A Nome newspaper has made the statement that Mr. Hamshower represents the Guggenhelms, and that he has secured an option on Mr. Manley's property on the basis of $10,000,000. This story is being freely circulated, and is entirely without basis of fact. Mr. Hamshower is in Mr. Manley's employ, has more than once showed the Guggenhelms, who have as much as they can comfortably assimilate. It is true that the extent of the property, and the lack of water, have led Mr. Manley to consider the transfer of a part of his holdings in exchange for working capital, for over $250,000 has been expended by him in preparatory work. Mr. Manley is now on his way to San Francisco and Boston, with a view to obtaining the capital needed to bring the enterprise to a successful issue.
In the Fairbanks district the general shortage of water has been such as to restrict the washing of gravel. On Dome, Vault, and Chatanika creeks, there are many 'dumps' awaiting treatment. Only on Esther creek are operations unhindered, and this is due to three or four large springs which feed the creek even after the winter snows on the divide. On No. 8 Below Discovery, Berry & Hamil are opening up a block 640 by 400 ft. by 'drifting' at a depth of 90 ft. The yield averages $1.50 per square foot of bedrock. Self-dumping buckets are used in conjunction with a steam-hoist. On the Reutter fraction, next to No. 3 Below, John Jesson is opening his ground at a depth of 85 ft., the gravel being partly on the creek bed and partly in the divides. On No. 8 Below Discovery, Berry & Hamil are opening up a block 640 by 400 ft. by 'drifting' at a depth of 90 ft. The yield averages $1.50 per square foot of bedrock. About 5 ft. of gravel and soft bedrock are extracted by 'drifting' in the usual way. At the other end of Esther creek, Mr. W. F. Green is doing a little prospecting on No. 6 Above.
On Cleary, the Discovery claim, being worked on a 50% lay by D. G. Atken and John Webster, has been yielding splendidly. The last two clean-ups were $14,700 and $19,000, respectively, for two successive runs of four days each. John C. Smith is working the bench claim on Discovery. Henry Riley is working 20 men on No. 11 Below, and is getting good results by drifting at 70 ft. On Goldstream, each shaft sunk is proving the further extension of the 'pay.' On 17 Below good pay has been struck at 80 ft. There is reason to believe that this part of the Fairbanks district will undergo important development.

JOHANNESBURG, TRANSVAAL.

The re-starting of milling operations by the Aurora West, in the poorer part of the Roodepoort district, is one of the most satisfactory items of the Rand's current mining news. This mine has, by reason of its comparative poverty, had a checkered career. It commenced milling in 1892, closed down in 1894, re-commenced in 1895, and again closed down upon the outbreak of war. Upon the introduction of Chi-
view that the engine was a factor of importance, and expressed the hope, in view of the contradictory character of the data collected, that the discussion of the matter would lead to the publication of experiences recorded by deep-shaft sinkers in other parts of the world. The discussion of this special feature of deep-shaft sinking has again raised the old question of the relative merits of sinking with buckets or with slips, the latter making for speed and the former for safety. The question is not one which lends itself to analysis on purely engineering grounds. The Brakpan and Cinderella Deep shafts were sunk with buckets, but in the Turf mines, now approaching 3000 ft., slips are being used, as was the case in the City Deep and Wolhuter Deep.

The French Rand has been obliged to declare a loss of nearly £2000 on operations for July. It is announced that in future the policy of the company will be changed, owing to the troubles encountered underground, and attention will be devoted primarily to the narrow, but rich, South Reef. This will involve a temporary curtailment of milling operations. A report on the mine's position is promised, but the ground is still of unapparent value. The Reef demonstrated in published records, points to the cause of the altered mining policy.

The demand for the thorough training of skilled men to serve the industry has led to the formulation of a more elaborate scheme of underground apprenticeship than hitherto attempted, which, in theory at least, promises well. Limited success thus far has attended efforts in the past to provide sound practical education on these lines, principally for the reason that opportunities, remuneratively more attractive, have been too plentiful to encourage youths to follow a severe course of general training. As the field gradually resolves itself into a gold-manufacturing industry, with an efficiency too high to allow the inexperienced to sink to the bottom, the necessity of responsible apprenticeship in the system must become, if not more popular, at least a more promising road to success. A three years' term of underground work is prescribed for youths of not under 18 years of age, and a scale of wages increasing half-yearly from 5s. to 10s., or 12s., per shift. The course is to include training in timber-work, pipe and plate-laying, hand-drilling, machinery-drilling, shaft-work, pump-work, and general mine duties. Such a range of application reveals at once the cause of former failures. The youth entering the mine under ordinary conditions applies himself to one branch of work, and thus gains proficiency and the skilled man's wage far more speedily than when he is called upon to be experienced in many departments. In other words, the temptation to immediate profit outweighs the prospects of future promotion to higher positions, in which an narrow experience is of small service.

By his vigorous plea on behalf of the South African trained mining engineer, Prof. Orr of the Transvaal University College, has raised a storm of protests which cannot be readily calmed without the aid of neutral peacemakers. The professor's plea was lividly by a bold attack upon the scheme whereby a few students of the Royal School of Mines, London, are placed on the mines at £10 per month, by way of a post-graduate course; students of the local college, he declared, were not given these special facilities. The committee of the Institution of Mining & Metallurgy responsible for this working of the post-graduate scheme has risen up in arms against Prof. Orr's 'intemperate' attack, and it seems that a warm controversy must follow, of little advantage to the cause either of the London or of the Johannesburg students. Different consulting engineers and managers naturally have different ideas as to the best field from which to draw recruits, and it is unlikely that any disputed arguments will affect these predispositions, whatever the benefits of a protective policy.

The statistics of mineral production for June, issued by the Government Mining Engineer's Department, include a record of results for the half-year. The yield of gold, approximately as declared by the Chamber of Mines, stands at a value of £14,456,652; of silver (from gold bullion), £41,571; and of diamonds, 1,015,155 carats, worth $3,015,155.

TORONTO, CANADA.

Activity in Cobalt Stocks.—Distinguished Visitors.—Excursion to the La Rose Mine.—Silver Queen.—Iron Furnace Closed at Port Arthur.—Algoma Steel Works Resumes.

On the stock market there has been an enormous volume of transactions in the leading Cobalt stocks, with a strong upward tendency. Never before has Cobalt had so many visitors of distinction as during the last few days. The excursion party of the Canadian Mining Institute, including British, German, French, and Belgian engineers, had a revelation as to the remarkable progress and resources of the camp. At the Crown Reserve mine they were given a spectacular display consisting of a pyramid of high-grade ore of about 35 tons weight, averaging 14,000 ounces per ton. One mass of 450 lb. went at £10,200, or at 29,000 oz. On September 6 sixty New York and Boston brokers came to Cobalt as the guests of the La Rose Consolidated, and inspected the La Rose, Nipissing, Crown Reserve, and other leading properties. The immediate result of their visit was the pouring in of orders, and a sharp advance in prices. The principal demand was for Crown Reserve, which has been secured from the La Rose Consolidated, and is expected to yield 2,000,000 oz. The principal announcement was that the Crown Reserve mine, and O'Brien's mine, will be worked. The Silver Queen mine has been sold to the owners of the No. 35 vein, which is 5 ft. wide, and heavily 'shot' with silver. On the Right of Way at a distance of 9 ft. from the shaft a 2-in. vein has been found native silver from which slabs of silver have been taken out. Another narrow vein was reached at 14 ft. which shows native silver. The new air-compressor plant at Crown Reserve is completed and the big vein is showing up well. The ore blocks out between the two shafts, distant less than 300 ft., is estimated at $35,000,000. The Silver Queen has put its full plant, including the air-compressor, into operation for the first time since the fire that destroyed the plant in 1907. The ore, which has been taken out of the earth and re-sunk, is now being carried to the mill for treatment. The property is in the hands of a syndicate of Detroit capitalists and is now ready to receive ore.

The Atikokan Iron Co., formed to operate blast-furnaces at Port Arthur, Ontario, with a capital of $1,000,000, has gone into liquidation. The plant has been closed for some time. The order for winding up was granted on the petition of Mackenzie, Mann & Co., of Toronto, who are heavily interested in the enterprise, to avoid the further loss of the property under judgments obtained by creditors. The Algoma Steel Works, at Sault Ste. Marie, which have been closed owing to lack of orders, will at once reopen. Several heavy orders for steel rails have been received.

MEXICO.

Increased Ore-Shipments.—San Toy Mining Co.—Affairs of Encinias Mines & Smelting Works.—Chihuahua Plant of A. S. G. & Co.—Mina Vieja.—Santa Eulalia Aerial Tramway.—Lead and Copper at Terrazas.

That the general conditions at the mines, at least in and about Chihuahua, are improving seems indicated from the fact that the ore shipped to smelter through Chihuahua during the month of June amounted to 7500 metric tons; in July, 11,106 and in August, 15,306. But few months last year exceeded this tonnage. The greater part of the ore...
going through Chihuahua comes from Santa Eulalia, and there was scarcely a shipper in that district who did not increase production during August, with perhaps the exception of the San Toy. The Imperial Company has been shipping 2400 metric tons per month, as compared with over 3000 tons previous to the May shipments; but the improvement in grade has more than made up for the short- age in production. The reported deal of this Company for the immense holdings of the Potosi Mining Co., which was said to involve $5,900,000 gold, does not as yet seem to have been consummated, though it is said to be still pending. It is understood that Donald R. Gillies, president and general manager of the San Toy, has bought, through S. G. Burn and R. J. de Morambert, for $345,000, the Florencia mine, in Santa Eulalia, owned by Enrique C. Creel, Governor of Chihuahua and Mexican Ambassador to the United States. That the transfer has actually been made cannot be verified. The Florencia has been held under the option for some but a year. Burns and Morambert, who, after developing a fine body of lead ore, had endeavored to sell it to the Encinillas Mines & Smelting Works, of Santa Rosalía (the re-organized Encinillas Mines, Ltd.), of which Mr. Morambert is then manager. The Encinillas came into prominence several years ago, largely because of the great amount of money spent, and the difficulties between the Florencia and the Compania de Almadan. A new corporation has been re-organized and the control turned over to J. Clarac for the French stockholders, who had charged irregularities in management. Mr. Clarac came to Chihuahua, secured R. J. de Morambert, a former agent of the American Smelting & Refining Co., as manager, and a new plant was promised. Mr. Morambert has now been replaced by J. L. Saint Diiez, for many years superintendent of the Potosi smelter in R. S. Towne. No new development, however, has taken place. The impression prevails that the chief French holders are afraid to put up their own money and are endeavoring to raise by the sale of stock sufficient capital to start up and make shipments of bullion abroad, to produce a favorable showing.

The Chihuahua plant of the American Smelting & Refining Co. is situated at Morace station, about six miles south-east of Chihuahua. It is now making regular shipments of bullion to New York. The yards are practically filled with ore, and a third furnace will be blown in before the end of September. This Company is shipping from Santa Eulalia an excellent grade of ore to the Chihuahua plant, and also to El Paso. The greater part of the ore comes from the Mina Vieja (with branches to Velardeta and Santo Domingo) to the railroad at Santa Eulalia, a distance of about two miles, has been made by the Trenton Iron Works, of Trenton, N. J. The first carload has been shipped, so that immediately upon arrival in Chihuahua the construction of the tramway will be started.

At Terlingua, about twenty miles north of Chihuahua on the Mexican Central, the San Rafael, owned by Corrigan and McKinney, of Cleveland, Ohio, is proving to be a large body of lead ore, and the Columbus, recently taken under lease by the same people, is showing up as a fine copper property. Corrigan and McKinney are negotiating with the Messrs. Creel, of Chihuahua, for the purchase of the Rio Tinto smelter (and possibly also the San Pedro) at Tommas, in order that they may smelt their own ores, which are almost self-fluxing. The Rio Tinto mines and smelter were taken under option last year, just before the drop in copper, by Martin J. Condón and associates, of New York, and a considerable preliminary payment made, but this spring it reverted to the former owners, namely, Governor Creel and associates.

TERLINGUA, TEXAS.

Production of Quicksilver.—Chisos Mining Co.—New Plant Installed.

—New Almaden Mines.—Extent of the Cinnabar District.—General Conditions for Work.

The production of quicksilver in the Terlingua district is constantly increasing. The first cinnabar discovery here was made about twelve years ago by a party of Mexicans who had crossed over from Mexico to hunt deer in the mountains. In the party were men who had had experience in mining. They were quick to recognize the cinnabar. They reported their discovery to two men named Wardless and Mendez, in Mexico. These men, in connection with Charles Allen and another named Case, organized a company and purchased two sections of land upon which the cinnabar prospects were situated. They did some development and sold the claims to James Norman, representing the Marfa & Mariposa Mining Co., for $125,000. This Company purchased additional claims, and developed the properties on an extensive scale. It erected two 20-ton furnaces, and for five or six years its net production of quicksilver amounted to $15,000 to $20,000 per month. Altogether it is said to have produced more than $300,000 worth of quicksilver since the mine was opened. As many as 200 men have been employed upon the property at one time. The mine is still being worked, but with a decreased force. The Marfa & Mariposa mine is situated about nine miles west of the Chisos mine. The workings have reached a depth of about 500 feet.

H. E. Perry, of Chicago, owns what is said to be one of the most valuable quicksilver mines in the district. During the few years that it has been operated, quicksilver to the value of $500,000 has been brought from a 10-ton furnace. In the beginning, retorts were used, and even by that primitive method the profits were large. The mine is operated under the name of the Chisos Mining Co., but it is stated that practically all the stock is held by Mr. Perry. The Chisos mine proved to be the richest and most productive mine in the Terlingua district. The ore is unlike that in the other developed cinnabar mines, in that it contains no free mercury. The ore is rich, some of it yielding as high as 30 to 40% of the metal. The average, however, is from 3 to 6%. But one shaft has been sunk, which is down 400 feet.

The Chisos mine is said to be superior in richness and productiveness to the New Almadan quicksilver mines of California. In order to increase the output of the mine, preparations are now being made to extend the shaft to a depth of 1000 ft. A new 20-ton furnace has been installed, and an ore-crusher of modern type will soon be placed in operation. One ton of ore will yield about one flask of quicksilver, worth about $45. The expenses of operating the mine are at present about $3000 per month.

Situated on the east side of Terlingua creek is the cinnabar property of the New Almadan Mining Co., which was financed in Dallas, Texas. This Company has invested about $300,000 in the erection of furnaces and in development work. It is now having trouble with water in its lower workings. The cinnabar mines of the Terlingua Mining Co. adjoin that of the Marfa & Mariposa Mining Co. on the east and north. This property produced quicksilver in considerable quantities for a time, but is not now being worked. The property of the Terlingua Co. was one of the first to be developed in the district. It was largely due to the energy and persistence of L. W. Deweoe of that Company that the richness of the district was finally brought to the attention of outside investors. He installed a 49-ton furnace, which did not, however, fulfill the claim made for it in the matter of treating low-grade ore, and the mines of the Company
were shut down. The cinnaabar property of the Big Bend Mining Co. is also situated on the east side of Terlingua creek. The Company installed a 20-ton furnace and had begun development work about three years ago, when its president, Will Study, died. His death caused an interruption of the plans of the Company, and the furnace has never been placed in operation. The Company has a great quantity of rich ore on the dump, and is said to own a valuable property. The Colquitt-Tigner Mining Co.'s claims are situated six miles northwest of the Chisos mine. This Company has a 10-ton smelter, and a large amount of ore on the dump. It ceased operations some months ago, but it is reported that it will start work again soon. The Lone Star Mining Co. is erecting a furnace, but is doing no development work at present. Adjacent to the mining district, and adjoining the promising claims which were originally owned by the Mc Kinney Bros., they passed into the hands of J. R. Holland, of Alpine, who recently sold them to the Chisos Mining Co. for $15,000. It is reported that they will be developed on an extensive scale.

In addition to the claims upon which development work has been done there are a number of good cinnaabar properties in the district. New mineral has been discovered on the east side of the Chisos mountains, about 65 miles from the nearest mine in the Terlingua district. The remoteness of the region causes development work to progress slowly. The State of Texas owns every alternate section of land in the mining district, and the mining law is so unfavorable to prospecting upon State lands that a mine is wholly confined to the lands held by private ownership.

The water and fuel problem is a serious difficulty. The water-supply for some of the mines has to be hauled from the Rio Grande, a distance of several miles, while wood is brought over from Mexico by Mexican wood-haulers. A good quality of coal is found in some parts of the district, which is a much needed addition in some of the furnaces. Some of the concerns have steam-plants, while others use gasoline. Alpine is the most accessible railroad shipping point for the mines. It is situated 100 miles north of Terlingua. The road is fairly good, but in case of rains it takes teams from six to eight days to make the trip one way. There is no stage-line to the district, and visitors have to get in and out the best way they can. The building of a railroad from a rich lead and silver district, situated in the mountains of Mexico about thirty miles south of Terlingua, through the Terlingua district, to a connection with the Southern Pacific railroad at Alpine, Texas, is now proposed. Enrique C. Creed, of Chihuahua, Mexican Ambassador to the United States, is the principal owner of the mines in the Mexican district referred to, and is backing the proposed railroad.

**SALT LAKE, UTAH.**

*Dividends Payable by Silver King Coalition.—Bullion Settlements.—Utah Copper Co.'s Improvements.—Washington County Oil Field.—Majestic Smelter in Beaver County.*

The Silver King Coalition Mines Co. has come into the limelight again through its return to the dividend list. A distribution of 50c. per share, or $187,500, will be made on October 1 to shareholders of record on September 29. The Silver King properties are at Park City, embracing over 2000 acres. A vigorous campaign of development has resulted in increasing the available tonnage of ore and the property is said to be in better physical condition than ever. Dividends are now expected quarterly. The ore and bullion settlements reported through Salt Lake banks last week aggregate $425,000, and the sales on the Salt Lake Stock & Mining Exchange amounted to 249,917 shares, representing $297,607. The Utah Copper Co. is acquiring surface rights to adjacent territory to be utilized as a dumping place for overburden removed from the porphyry-ore deposits, and to make room for additional trackage. For $17,500 the right to use 29 acres for the purpose stated has been acquired from the Little Eddy and the Puritan Gold & Copper companies, which followed a purchase made recently from the Bingham Amalgamated Copper Co. The right of way for the proposed extension of the Bingham & Garfield railroad, a subsidiary connection to the Utah Copper Co., will cross the ground acquired.

During the past year much attention has been paid to the opening of a new oil district in the eastern portion of Washington county near Virgin City. A half dozen producing wells have been brought in, and an Eastern syndicate has secured a foothold and will install many new rigs shortly after the close of the year. The oil is a high-grade lubricant.

Rumors have been persistent this week that the smelter owned by the Majestic Copper Mines Co., near Milford, is to be placed in commission soon. The plant is equipped with one copper furnace and one lead stack. The original promoters of the Majestic built the smelter to help boom the stock which was at fancy prices. The smelter is now under construction in Beaver county and soon will be in operation.
Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Tailing is the property of the person from whose works it issued, if retained on his own land. When allowed to flow upon another's land, the owner of the land is entitled to the tailing, and may sue for damages.

Metal mining is more injurious to the health of miners than coal mining. The inhalation of coal dust produces pulmonary difficulty in time, but not so promptly as the dust from metal mines. The increase of dust from the use of power-drills has greatly augmented this difficulty.

Water softening, where the hardness is due to lime sulphate, may be accomplished by the addition of barium carbonate. Barium sulphate is produced and lime carbonate forms, both of which are nearly insoluble, and will precipitate. Barium hydrate may also be employed, which has the advantage of decomposing the lime salt with the formation of CaO, which will reduce the soluble lime bi-carbonate to the insoluble carbonate. The high cost of barium salts is an obstacle to its wide use for this purpose.

Refractory brick for lining reverberatory furnaces, lime-kilns, and the like, may be made from bauxite, for which purpose as pure a grade as that used in the manufacture of porcelain is not necessary. To make such brick, wash the bauxite to remove free silica, and then calcine the material thus floated off, at a temperature of 2500°F. Mix the minimum quantity of very pure washed fire-clay needed to effect a 'bond,' mold, dry, and burn in a down-draught kiln at a high temperature. About 3% of hydrated lime may be used for 'bonding' instead of fire-clay.

The largest stone crusher ever built, according to the best advices attainable, is operated by the Dixie Portland Cement Co., at South Pittsburg, Tennessee, and was built by the Power & Mining Machinery Co., Cudahy, Wisconsin. The crusher is 18 ft. 11 in. high and weighs 425,000 lb. Pieces of rock 3 by 5 by 10 ft. can be crushed by this machine to 6-in. size at a rate of 800 tons per hour. The crusher is of the gyratory type, and is positively operated by an eccentric completely submerged in an oil chamber. The crushing-head is 65 in. diam. at the bottom, 6 ft. 9 in. high, and weighs 32,000 lb. The lower shell of the crusher is a single casting and weighs 73,000 lb. The heavy and expensive parts of the machine are protected by renewable steel and white iron liners wherever abrasion takes place.

Lime is frequently used in place of an explosive in coal mining, particularly in Europe. Pure calcium oxide (CaO) ground to a fine powder is made up into a cartridge 3 to 4½ in. long, with a groove ½ in. diam. on one side. An iron tube ⅓ in. diam. and perforated on the upper side, is inserted the whole length of the bore-hole. This tube is inclosed in a calico bag which covers the perforations and one end of the tube; the other end is fitted with a tap. The cartridges are then pushed to the back of the drill-hole and tamped in the same way as an explosive. A small force-pump is connected with the tap at the end of the tube by means of a short flexible pipe, and water equal in bulk to the quantity of lime used, is forced in. The water escapes through the perforations as it passes along the groove, and the lime in the cartridge is saturated, the tap is closed, steam is generated, and the combination of generating steam and expanding lime brings down the coal.

Feldspar is in demand on the West Coast for the manufacture of porcelain. Prospects will do well to look out for commercial deposits. These may be found in any granite region, particularly where pegmatite dikes are frequent. The existence of much free silica, and particularly of basic accessory minerals, such as hornblende, pyroxene, and mica, renders the feldspar unfit for the purposes of the potter. A deposit should be very carefully sampled, knocking off the weathered surface, and taking fresh rock only. As examples of commercial feldsars the following analyses are given:

<table>
<thead>
<tr>

Any of these would have a market value, but it may be indicated that in No. 3 the Fe₂O₃ has reached the maximum permissible.

Triangular weirs for the measurement of the flow of water are practical only when the quantity of water is small. The coefficient by which the theoretical discharge must be multiplied to obtain the actual discharge varies less with changes of the head for triangular weirs than for those of the rectangular form. These coefficients have been investigated only for weirs in which the lower vertex is a right angle. The theoretical discharge for such a weir may be computed by the formula:

\[ q = 0.538c \sqrt{2gh} \]

in which \( q \) is the discharge in cubic feet per second; \( c \) is the coefficient of discharge; \( g \) is the acceleration of gravity in feet per second; and \( H \) is the head, in feet, on the vertex of the weir. As a result of experiments by Thomson, the mean value of \( c \) for heads between 0.2 and 0.8 ft. may be taken as 0.592, and hence the mean discharge through a right-angled triangular weir may be written

\[ q = 2.53\sqrt{H} \]

The usual precautions for other forms of weirs must be observed. The inner corners of the weir must be sharp, the contraction of the stream must not be suppressed, there must be no velocity of approach (or else it must be allowed for): and the head, \( H \), must be measured several feet back from the weir.
Discussion.

Readers of the MINING AND SCIENC TIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

Methods of Sampling Ore in Place.

The Editor:

Sir—Sampling of mines and prospects, by many mine foremen, and even by some engineers, is not done with sufficient care to reveal the truth as to the value of the ore sampled. There are several inadequate methods in vogue for sampling the face of a drift. Among them I will mention three of the commonest: (1) The grab sample, in which the sampler merely picks handfuls of the ore from various parts of the muck-pile resulting from the last shots; (2) the ‘hit or miss’ sample, in taking which the sampler picks down loose portions of the face here and there until he has filled his sample sack; and (3) the channel sample, in taking which he carefully cleans the face of the drift and, with a mull, chips off a uniform channel across the face, catching all that drops in a canvas spread for the purpose.

If the material sampled is thoroughly homogeneous with respect to the metallic content of the ore, either of these methods will give a sample that, when assayed, will indicate correctly the average quantity of the material in the face. But, unfortunately or otherwise, the material sampled is seldom of a homogeneous nature. If rich streaks of minerals occur, it is evident that a sample taken by any of the above methods cannot be correct, for the reason that a proper proportion of the rich material will not be included in the sample, thus causing the results to be either too high or too low. A small piece from a streak of bornite rich in silver, or a little too much broken from a 2-in. streak of chalcopyrite, will cause the sample to indicate too high a proportion of silver or copper, while a failure to include a large enough proportion of these rich minerals will cause the sample to run too low.

A much more accurate method of sampling the face of a drift is to take several samples, each one being a sample of one of the various streaks, bunches, or bands of ore, and to calculate the average metallic content of the material in the face from the assay results obtained from the several samples. The face of the drift should first, by careful inspection, be divided into separate bands or streaks, each one approaching a homogeneous condition as near as may be possible. These bands or streaks should then be sampled separately by taking a channel-sample across each streak, and noting the exact width of each sample in inches. After assaying, the average of the ore sampled may be determined, by multiplying the per cent of copper or other metal in either percentages or ounces per ton, by the width in inches of that particular sample, adding the several products, and dividing the result by the sum of the several widths sampled. For instance, supposing a sample to have been taken across a 5-ft. orebody containing three bands of ore of different quality, and supposing the assayer gave results as follows:

<table>
<thead>
<tr>
<th>Width</th>
<th>Silver sampled. per ton.</th>
</tr>
</thead>
<tbody>
<tr>
<td>36 in.</td>
<td>10 oz.</td>
</tr>
<tr>
<td>2 in.</td>
<td>1000 oz.</td>
</tr>
<tr>
<td>22 in.</td>
<td>30 oz.</td>
</tr>
</tbody>
</table>

\[
\begin{align*}
36 \times 10 &= 360 \\
2 \times 1000 &= 5000 \\
22 \times 20 &= 600 \\
60 &= 3020 \\
3020 + 60 &= 3100
\end{align*}
\]

This results in an average of 60 in. of 50-oz. ore. If the small 2-in. streak of high-grade ore had been thrown out, the average for 58 in. would have been about 17 oz. per ton, hence obviously unfair to the property sampled. If the whole sample had been taken as one, and twice as large a proportion of the rich 2-in. streak had been included than was proper (it is impossible to get this proportion to approach correctness), the resulting average for the 60 in. would have been about 83 oz. per ton, which is obviously too high a result.

An advantage of using this method of sampling, even when the proportionate richness of the various bands of ore cannot be determined by inspection, is, that after the assay results have been obtained, an idea can be formed, by constructing an assay map, of the form of the ore-shoot, often resulting in the finding of ore of a paying quality where other methods of sampling would have indicated ore of too low a grade to pay.

El Paso, Texas, August 5,

Technical Education.

The Editor:

Sir—I was much interested in the editorial on ‘Technical Education’ in the MINING AND SCIENTIFIC PRESS of June 13, and have since reflected that a reason for the rather general criticism of present-day technical education lies in the fact that it is straddling the fence between two incompatible fields of endeavor. The one is that which you urge should be more adequately covered, which, when it is summed up, is the making of a really educated man; the other is the making of a highly specialized workman. Now which should we have? You cannot make a silk purse out of a sow’s ear, and you cannot educate some men. I am thinking at this moment of a man who has his doctor’s degree from a well known university, but who is actually less educated than a good horse. Then there are other men who are educated, but who never went to school. Others again could never become specialized workmen; they could never become good assayers; they could barely hold their jobs at running a drill or as shift-boss in a mill; yet they can manage mines, and in general fit the standard of your editorial.

We need both types of men, and we can solve the problem very simply by giving two kinds of courses, one in pure technique for the workman type, and a really educational course for the other type. Not one man out of twenty is a competent judge of what he is fitted for when he enters college, and his
parents are usually less able to judge, for they think he is what they want him to be. So each would be taking the other’s course, and I fancy the net result would be much the same as now. Is there any better method than giving the undergraduate what he must have, and telling him to get what else he needs for himself? I think personally that certain things that he now has to get for himself had better be included in his course, above all the business side of mining and metallurgy; all our young graduates are deplorably weak in that. On the side of general education, courses in political economy, logic, and psychology are almost equally needed. But when you almost have to use force to get the festive undergraduate to take his courses in calculus and mechanics (since he wants ‘practical things’), how shall you make him submit to psychology? ‘I interrogate for enquire,’ as Hashimura Togo would say.

Certainly our present methods of technical education need tinkering as badly as does the tariff, but I must confess I do not know just how it ought to be done. Why not give it to the new Mining and Metallurgical Society to cut its teeth on? That body ought to be able to fix it, if anybody can.

Montana Mine-Owners’ Association.

The Editor:

Sir—I notice in your issue of August 29 that one of your correspondents stated that there seems to be something wrong with the Montana Mine-Owners’ Association which was organized to fight the smelter trust. We do not know where your correspondent got his information. The officers of this Association made arrangements with the Idaho Smelter & Refining Co. to work the ores of the Association and any non-members throughout the State of Montana. During the month of August Thos. L. Greenough purchased the interest in the Idaho Smelting & Refining Co. of J. Herbert Anderson. Mr. Greenough is vice-president of this Association, and his company will work our ores on the same terms and under the same agreement as we made previous to his purchasing Mr. Anderson’s interest. The officers of the Montana Mine-Owners’ Association did not think it was necessary to publish all their acts and doings to the public, as each of the officers has spent his time and money to further the interests of the Association and has gone about the work in a quiet way. Nearly all our members who have ore to ship are forwarding it to the Panhandle smelter, and seem well pleased with the results. The officers of the Association are putting in their time gratis, and we hope to accomplish many other results, but do not care to publish in advance what we expect to do in the future. The Panhandle smelter is now receiving thousands of tons of ore monthly, and will be ready to blow in a plant on or before October 1. We are not out for the purpose of fighting the trust, but for the simple object of getting lower smelter-rates, to give relief to the mine-owners of this State. There is plenty of room for the A. S. & R. Co. to keep its plant going, provided they adjust their rates on an equitable basis, so that the mine-owners can live and make a little money besides. I hope this explanation will give satisfaction to some of your readers.

R. A. Bell.

Helena, Montana, September 8.

Tailing Wheels Compared with Centrifugal Pumps.

The Editor:

Sir—The accompanying photograph conveys a good idea of the construction of a tailing wheel, designed and constructed at the works of the Smuggler Union Mining Co., by M. R. Hansen, the master mechanic. It is of the internal-bucket type, and weighs 13,679 lb. It is 24 ft. diam., over all, containing 92 buckets, makes five revolutions per minute, elevating 225 tons of sand and 2775 tons of water each 24 hours, and requires 8 hp. with a full load. The wheel is mounted on a 7-in. shaft, resting on two bearings, 8-ft. centres, and is driven with cog-gears, making two speed reductions, on acounter-shaft which is belted to the vannier line-shaft. The hub is cast in two pieces bolted together, allowing the spokes, made of 3 by 4 by 1\(\frac{1}{4}\)-in T-iron, to fit between the two sections of the hub. The rim is built of two circles of 3\(\frac{1}{4}\) by 2-in. angle-iron and \(\frac{3}{4}\)-in. sheet-steel plates, lined with pine lumber, this lining forming a part of the buckets and taking all of the wear from the sand. Each section of the rim is braced with 1\(\frac{1}{4}\)-in. rods running to the outer ends of the axle. Judging from several years’ operation of the old wheel, which was not as well constructed, the repairs, aside from the annual renewal of the buckets, at a cost of $100, will be of no consequence. It seems quite safe to count on at least 10 years as the life of this wheel. For fifteen months prior to this installation, the tailing was pumped with a centrifugal pump. This proved more expensive and very unsatisfactory, owing to the frequent stops for repairs, and the necessity for often changing the speed to get a
regular discharge. The following costs of installing and
operating the wheel, as well as the same for
pumping, give a comparison which may prove interest-
ing to others as a vindication of the excellence of the
tailing-wheel.

**Mine Investments and Ore Reserves.**

The Editor:

Sir,—To be a paying investment a mine should
eventually return the capital invested, with interest
at a per cent thought to be equal to the risk. While
the bank-rate for deposits is 4%, and 8% can be ob-
tained on good securities, 20% is the minimum inter-
est considered safe in mining investments. Prop-
erties which are thoroughly developed, with reserves
of ore that can be accurately measured, and the profit
figured to within a few cents, may not require
this high rate. English investors consider 25 to 35%
rate as fair on mines in this country.

Gold mining is not more risky than mining for
the base metals, for while subject to irregularity of
metallic content, there is no variation in the market
price. Gold mining, when conducted on the same
lines as mining for coal, copper, or lead, offers as
good or better inducements to capital awaiting in-
vestment, but the lure of gold often leads good busi-
ness men into absurd methods of financing and oper-
ating. Too often, as long as a mine pays its way, the
feast is considered so meritorious that the sharehold-
ers’ right to expect a dividend is not considered at all.

A mine, to be considered an investment, must re-
turn the original money invested, with compound
interest, until the mine is exhausted, together with the
minimum per cent of interest per annum, which
should be 20%. The life of a mine, or the time it is
worked until it is exhausted, will depend upon the
amount of ore blocked out and that to be developed,
divided by the rate at which it is mined. Without
considering special cases, this time may be consid-
ered as seven years. The mine, then, must pay suffi-
cient dividends to redeem the capital at compound
interest in seven years, with interest at the rate of
20%. This redemption or depreciation-fund may be
invested by the company and returned when the mine
is exhausted, or returned to the shareholders in the
form of dividends. There are many objections to
the former procedure.

To take a specific case, what should be the amount
of dividend from a gold mine treating 75 tons of ore
per day, in which $200,000 has been invested, so as to
constitute a safe investment, and what profit per ton
should be realized? A sum of $200,000 invested in
commercial securities will safely net 5%, which at
compound interest for seven years will amount to
$281,415. To pay back the original investment,
$40,200 must be returned each year for seven years.
Interest at the rate of 20% will require $40,000, mak-
ing a total of $80,200 per year. If the mill treats 75
tons per day, in a year of 360 days, it will treat 27,-
000 tons. The profit of $80,200 per year, divided by
27,000, gives approximately $3 per ton. Should the
profit be less, the ore must be sorted more carefully,
the extraction in the reduction plant must be raised,
the operating expenses reduced, or the plant enlarged.
It is safe to assume that the first two contingencies
will have been attended to. The operating expenses
include mining, milling, superintendence, and devel-
opment. Of these, only the last will claim attention,
for it may be assumed that the other expenses are at
their minimum.

Development means reserve ore. All profits from a
mine might be put into development, and unfortu-
nately this is often done. The question then is, how
much reserve ore should be on hand. By ‘reserve
ore’ I mean that which has been opened up so that
it can be measured and sampled on two sides of a
triangle, or three sides of a square the sides of which
are not longer than the horizontal length of the ore-
shoot. The answer to this question will depend upon
the character of the deposit, the depth to which it
has been developed, and the tonnage of the reduction
plant. The deeper the mine is developed the less ore
reserves will be necessary, until the mine is exhausted
in the hypothetical seven-year period. The mine
is then exhausted at the rate of 428 ft. per year. A mill
treating 75 tons per day will in one year exhaust 428
ft. of vein along the ore-shoot if the vein be 2 ft. wide
and the ore-shoot 410 ft. long.

Half the capital invested will go into development
and equipment, for it is a fair assumption that the
mine was not bought nor the equipment ordered un-
less there was blocked out ore that would return a
profit of at least $100,000 at say, $2 per ton profit, or
50,000 tons of ore. The ore in the mine must then
have been blocked out to about 800 ft. in depth, yield-
ing sufficient ore to supply the mill for 22 months.
By the time this supply has been exhausted the res-
erves should be developed about 580 ft. deeper, or at
1380 ft. This will give 16 months’ reserve. When at
2000 ft., 270 ft. more must be opened up, giving 7
months’ reserves. The amount of development neces-
sary to keep ahead of mill-needs is now seen. In the
first 22 months the shaft must be sunk 580 ft., and
the drifts at this level extended to the limits of the
ore-shoot. If the shaft be in or near the ore-shoot,
the work required will be about 30 ft. of shaft, 100 ft. of drifts, and 30 ft. of raises per month. If the mine management is doing more than this, and the mine is not paying as it should, the development may be cut down to this minimum. If the mine cannot afford this, it may be classed as a poor investment, unless by enlarging the plant a sufficient reduction in expenses can be made.

The sooner a mine is exhausted the greater the profits, granting that ore can be provided fast enough. If the capacity of the hypothetical plant is doubled, the mine will be exhausted in 3½ years. Now, $200,000 at compound interest at 5% for 3½ years gives $237,312. This divided by 3½ gives $67,800; plus 20% interest, is $107,800, which must be paid each year in the form of dividends to redeem the capital and pay a fair rate of interest. The only saving attained by doubling the capacity of the plant will be in the running expenses, which may possibly, but not probably, reach one dollar per ton. The reserves necessary may be doubled.

Many pretend to believe that for every ton of ore taken out of a mine two should be developed. As there is a limit to which mining may be profitable, the absurdity of the idea need not be insisted upon. My theory is that as a mine is limited in ore available, the amount necessary to be kept in reserve should diminish from the year when the maximum of safety has been reached. If we start with no ore in reserve, then it should be developed faster than for one or two until the point of safety is reached. A mine in the development stage, with no reduction works, will in most cases have a two years' supply of ore on hand. This anach is generally required before a mine can be sold, or before a mill is justified, and taking this as a starting point, if the other data are known, the dead work necessary to keep the mine going until exhausted may be figured.

Suppose a mine with a 400-ft. ore-shoot, 5 ft. wide, to be opened up to 1000 ft. in depth along the vein, and that the mill treats 100 tons per day. Suppose the mines in the vicinity have become unprofitable at 4000 ft., or, in lieu of all evidence to the contrary, it is deemed that the pay ore will last to that depth. How much dead-work should be done the next year?

A mill treats a hundred tons per day, or 72,000 tons in two years. This is 938,000 cu. ft. The ore-shoot being 400 ft. long and 5 ft. wide, must be blocked out for 475 ft., so that the ore has been exhausted from the surface to 525 ft. in depth. If the mine is to become exhausted at 4000 ft., and if it be accepted that a safe amount of ore on hand to start with may vary in inverse ratio to the depth, then the following or third year the mine should be developed to 1356 ft.

The formula I use is:

$$X = \frac{R(D-d)}{D}$$

where \(X\) is the reserve necessary at any given point, \(R\) the ore for two years' supply from the starting of the mill, \(D\) the depth at which the mine becomes unprofitable, \(d\) the depth of the mine at the time the reserve is reckoned.

This mine will have a life of over 20 years, and the capacity of the plant, as well as the reserves, should have been increased. Very few orebodies are so simply constituted as here portrayed, so the amount of development work necessary would vary, and instead of reckoning in feet of depth it would be better to convert to tons of ore. I used the former for convenience. The theory that the reserve should grow less as the limit of profitable working is reached allows for the increased cost of working at greater depths to be taken out of development expenses.

**Algeron Del Mar.**

South Pasadena, California, September 5.

**Professional Ethics.**

The Editor:

Sir—In answer to the question asked by ‘Constant Reader’ in your issue of August 29, Mr. Probert draws the comparison between the engineer disseminating information, obtained while in the employ of a company, which was to the discredit of that company, and the physician making use of previously obtained knowledge in the treatment of a case. Would it not be a closer parallel to compare such an engineer to the doctor who gives out information obtained professionally, which is injurious to the chance of the patient? I dare say such a physician would be in no little demand in the same cases, as would be the confidential man in business who made public his employer’s methods.

There are even closer comparisons to be drawn from the few rules established by custom among mining engineers. A consulting engineer is employed to advise as to the method of treatment of an ore, or the operation of a mine. The information he obtains regarding that property, and the conclusions he arrives at belong to that company. If it were part of his duty, or even his privilege, to make public any error he might discover in the management, or financing of that company, the demand for professional service would be greatly lessened. It would hardly be professional for an engineer to examine and report on a property for one client, and then to sell his report to a second client. This second client might, as in the case cited by Constant Reader, be going to invest too small an amount to warrant a separate investigation, but that would in no way affect the reporting engineer.

Why should the young engineer, employed by a company, in a subordinate position, be allowed greater latitude than his more eminent confrères? From my own point of view, such an action as that under discussion would be both unprofessional and unbusinesslike. True, it might save the one small investor from a bad investment, but that the mining industry would be benefited thereby I question. It is not through such actions that we may hope for the universal adoption of the open-door policy in mining, but through a realization of the fact that the engineer is working for the best interests of his company in whatever capacity he may be employed, and a recognition by the investing public of the beneficial results from such service.

**Sumner E. Brown.**

San Francisco, September 8.
TREMAIN STEAM STAMPS.

Written for the Mining and Scientific Press
By Cyril E. Parsons.

In southern Rhodesia more than forty small Tremain stamp-mills are in constant operation. They are light, portable, and self-contained, though they consume a large amount of steam, in other words, fuel and water. This is not so serious where the plant is small, fuel cheap, and the available amount of ore limited. In Rhodesia they occupy quite an important position in the gold-mining industry. As soon as the royalty-system of payment was introduced into this territory, numerous small producers appeared as if by magic, and the industry received a great impetus. The majority of the deposits, it must be remembered, are small; the owners could not face a large capital-outlay; in many cases small deposits, containing only a few hundred tons of moderately high-grade ore had to be dealt with; and consequently a demand arose for a small machine which did not cost much.

High railway and transportation rates emphasized the necessity for some portable mill. A barrel of cement, for instance, which at the port of Beira costs 14s. 6d., delivered to the property costs 6s. In other words, third-class goods, which include the majority of ordinary mine stores, cost £12 per ton for railway freight alone.

The Tremain stamp-mills weigh 3300 lb. They consist of two stamps, the upper ends of the stems being two pistons moving in cylinders actuated by steam. To the lower ends of these stems, shoes are attached, each stem and shoe, when new, weighing 300 lb. The machine is worked by steam direct at a pressure of about 110 lb., and the stamps work in a mortar with front and side discharges. At Salisbury, the capital, the whole outfit, comprising a mill, amalgamating-table, and a 10-hp. boiler, can be had for £540, and with another £200 erection and extra expenses can be provided. The entire plant would weigh about eight tons. The foundations are usually inexpensive. The makers recommend a pile 12 ft. long and 30 in. across, but shorter lengths, of 9 ft., answer well, depending a good deal upon the nature of the ground. In one instance a 9-ft. pile was cut out of the trunk of a tree severed above the fork; thus two legs appeared at one end. This end was placed downward in the prepared excavation, with the idea that the splay increased the rigidity of the pile. On the prepared and level face of the pile-block rests the mortar, with an intervening piece of blanket, rubber-insertion, or even buck-hide. The boiler is set on rough foundations, as near the mill as possible, to avoid loss of steam through condensation, and to ensure a constant supply of dry-steam. A small automatic rocker feeder is usually provided. These are easily adjusted, and work well if the ore is clean, but are apt to break and jam with mixed clayey material. A rock-breaker is a distinct advantage, but necessitates a small auxiliary engine, which, in districts where native labor is cheap and plentiful, can be dispensed with. As a substitute, 'niggers' are employed to 'spall' or break the rock to the required size, which is that of a walnut, by hand labor. The mill often has a dilapidated appearance, with a few sheets of old battered second-hand corrugated iron to house it, supported on crooked native wood-poles (for straight timber in that country is unknown). Scantily attired natives may be seen moving leisurely about, while the white man may be underground, at the mill, or in his hut close by, snatching a few hours' rest.

Accurate accounts are seldom kept, and consequently it is most difficult to compile reliable data. The life is undoubtedly hard, especially in the rainy season and during the hot and more unhealthy months, which are April, May, and June. The men in these outside camps, living away from decent conditions and comforts, frequently suffer from malaria, camp-fever, or 'black-water,' and these severities are accentuated when the venture is a bad one and money is being lost. All sorts and conditions of people are found working these plants, and the individuality or character of the individual is quickly evident from the manners and system that surround his small undertaking. The catalogues furnished supply a fund of information, but their statements as to results should be accepted with a grain of salt. The cases described in this article are actually a collection of notes taken at different periods on the spot, and they represent as closely as possible the results obtained while they were written.

First case; one Tremain mill was operating, crushing 10.9 tons per day, being a duty of 5.45 tons per stamp. With this plant the consumption of oil was 20 gal., costing 3.9d. per ton of ore crushed. This, however, included oil used on a hauling engine and small steam-pump, as well as on the mill. The fuel was wood and cost 12s. per cord, and it took 85½ cords to crush 323 tons, or 3s. per ton. Shoes and dies came to £7 10s. 6d. per month, being four shoes and two dies, at 22s. 6d. and 30s., respectively. The ore was a fairly hard, oxidized quartz.

Second case; the mill was berched on the side of a steep hill, and the boiler, an ancient specimen, showed a pressure of 120 lb. steam, because, besides supplying the mill, it was working a pump at a level 100 ft. below the mill, and was throwing water from a stream to the mill. The fuel consumption was 2½ cords per day, costing 12s. 6d. per cord; the shoes lasted three weeks, and the dies four weeks, crushing hard quartz through a 20-mesh screen. In this instance the owners seemed uncertain what tonnage was being treated. In fact, they were very uncertain about the consumption of most of their stores.

Third case; the mill was in the Penhalonga valley, near Umtali township; fuel was very scarce, and cost £80 per month (at 25s. per cord). The owners considered that the mill dealt with 12 tons per day through 20-mesh, but they had never taken any careful measurements. The ore was oxidized quartz and schist.

Fourth case; fuller data were obtainable; the mine and mill were on sloping ground, close to each other, in thick 'bush-veldt,' 10 miles from the railway and 1200 yd. from a large river, which furnished the water. Two white men and about 70 natives were at
work; at the outset a mechanic was engaged to erect, start, and work the mill, but in about three weeks the owner learned to handle it himself.

The original outlay may be summarized as follows:

</tr>
</tbody>
</table>

The figures given make no allowance for owner's time, and a few other smaller charges appear to be omitted. It will be seen that 'stores' occupy a high percentage of the total costs. In Rhodesia fully 40% of the total expenditure goes to 'stores,' owing to the high freight and rates. The average cost for five months of native labor came to 26s. 3d. per head, while the food-consumption worked out at 2.7 lb. of meal per head per day. Each individual does not consume more than 2½ lb. The mill was worked by one 10-hp. boiler at 100 lb. steam-pressure, making 170 blows per minute. The cutting price of wood fuel per cord for 4 ft. lengths is 4s. 6d., and for 2½-ft. pieces it is 6s. The consumption amounted to three cords per day, but this includes wood burned at the pumping station previously mentioned.

The ore was schist and quartz mixed, and the mill crushed 10 tons per day through 26-mesh screens which were bursting daily at first, due to over-feeding, and from the same cause the guide-blocks wore badly and had to be raised. Under normal conditions 26-mesh screens lasted 2 days, and 24-mesh 3½ days. Soft ore seemed to make the dies eup.

The silvered copper plate provided with the mill measured 9½ by 4 ft. and was set with a drop of 1½ in. per foot. It was scraped daily and dressed every six hours. The oil consumed was 10 gal. per week, costing 2s. 8d. per month. The sight-feed lubricator attached to the steam-pipe is one of the most important factors with the mill. It must be carefully attended to, and adjusted, for in many cases it can be seen going wrong, owing to the vibration, and as soon as the steam-stamps are insufficiently lubricated they practically cease to work. At this mill from two to three drops per minute was the allowance. The amalgam yielded 37.3% bullion having a fineness of 800. With this mill, as well as others in the country, feeding mercury into the mortar-box is practised, but the advantages are not apparent. The loss or consumption of mercury from the crushing of 720 tons, yielding 305 oz. fine gold, was 4.8 dwt. per ton. The tailing assayed 4 penny-weight.

Selecting one month when the output was worth £453 17s. 9d., we find the following payments had to be faced, and these may be regarded as a fair example:

Total .................................. 7 12 6

From these figures it will be seen that the Government fee reached £216 0s. 10d., made up from claim licenses and royalty. The best run of mills was 24.3 days in a month of 31 days, but in this case loss of time was in a great measure attributable to having only two white men.

The joint between the mill-cylinder casting and the valve-chamber should always be well made. In the present case brown paper and thin canvas were both tried, but are stated to have been unsatisfactory. Eventually woven asbestos and graphite, also card-board and boiled linseed oil, were used, and answered well, the former lasting one month. The foundation block was buried only 7 ft. deep, and the automatic feeder was dismantled, since it did not suit the ore. Between the boiler and mill 26 ft. of uncovered steam-piping could be seen. The natives engaged were distributed as below:

About 800 to 1000 gal. of water were being pumped from the river and used each hour.

Fifth case: 30 miles beyond the last mine was another Tremain mill at work, under different conditions. The mine workings are on the top of a rugged hill covered with vegetation, and around it deep valleys have been eroded. The mill was on the bank of a large river 450 ft. below, and water for milling was raised by a small feed-pump a distance of 120 ft., delivering water into a 400-gal. tank. A 10-hp. Colonial boiler was connected to the Tremain by 20 ft. of exposed piping: the same boiler, besides its own feed pump, served the pump, raising water from the river, but steam was condensing badly and the boiler foundations were disintegrating; the boiler looked as if it were going to tumble into the river. One drop of oil was being fed for every 40 blows the stamps made. The mills are invariably connected to the steam-pipe from the boiler by a loop of 1-in. piping; this is done to take up the vibration, contraction, and expansion. In spite of this loop, in every case described, this tended to loosen the joints and to throw the sight-feed lubricator out of adjustment, and, as stated before, when lubrication is deranged, the mill gives no satisfaction. Flexible steam hosing would be an advantage instead of the iron looped pipe described, but oil ruins it quickly. Probably a loop of 1-in. copper piping would answer better. The steam exhaust must be carried away from the mill, and escaping steam checked, since it is charged with oil and gives onto the plates, interfering with amalgamation. Attention must also be paid to packing the rod projecting through the steam-chest ends. This chest contains the slide-valves operated by the ex-

haust. The joint between the steam-chest and the cylinder on this mill was made with red-leaded canvas, and lasted three months; the makers recommend a paper gasket, but this did not answer on the mills referred to. Ore was conveyed from the mine to the mill in a two-wheeled cart, taking two tons per load. Six mules were kept, two working at once, each taking three loads. Altogether nine loads were delivered per day, and eight loads were sufficient to keep the mill going. It was 1200 yd. from the mine to the mill, and the ground dropped 350 ft. The mules were rationed with 6 lb. of 'measleys' (maize) per day, at 30s. per bag (203 lb.). The monthly cost was as follows: mules' feed, £8 10s. 0d.; native driver, £3; total, £11 10s. 0d. Cost of transportation would be made up as follows:

This comes to about 5s. per ton. One year's purchase sounds drastic, but these mules are usually old, and are often destroyed by lions. Stores were carted six miles from the railway, this costing £4 per month. Fuel worked out at 21 per cord, because it was being carried to the boiler by Kaffirs. This took 15 natives, and the total outlay in this direction was £30 per month (including food). The fuel-consumption was 1½ cords per day, or 3s. 8d. per ton. Steam-pressure at the boiler was about 100 lb., and the running time per day averaged only 15 hr., due to old and faulty boiler-fittings. The mill was crushing 8 tons per day, but with a higher pressure in the boiler and better running time there would probably have been no difficulty in getting through 12 tons. At 100-lb. steam-pressure the mill made 140 blows per minute, whereas 200 would have been a reasonable speed.

For 112 tons crushed, shoes and die cost £6 7s. 6d., or 1s. 1d. per ton. Twice a month a clean-up took place. On this occasion it was usual to recover about 15 lb. of drill steel. The mine-smith was a native and probably burned his drills frequently. At one of the clean-ups the amalgam obtained from mortar-box was 22 oz., from the mercury trap 5, and from the plate 78 oz. From this amount 41 oz. of retorted gold was recovered, worth £4 per ounce. Inside plates were being used, and the mercury was fed into the mortar-box. The screens lasted 40 to 45 hr. by reversing. Tailing passed through a mercury trap and over a short-line of blanket-strafes. A panning of the tailing taken below the blankets showed considerable losses from floury mercury.

The Tremain mill, with its parts as originally supplied, were good material, but the complaint was that the spare parts supplied to replace the worn-out portions were inferior in quality. Generally these mills are useful in countries like Rhodesia, where transportation is a serious factor and the deposits are small, but there is no doubt that they render excellent service. As regards running-time, they would not come up to the standard of ordinary gravity-stamps. Inside amalgamation in the majority of cases would seem to be a mistake. The lip-plates supplied and
fixed to the mortar seem unnecessary. Complaints are sometimes heard as to the difficulty of keeping the shoes of an even length, but this can be overcome by ordinary care, and the fact that one man can keep one of these machines in perfect working order while at the same time attending to many other details, shows they can be handled easily. Among the points deserving close attention are, the projecting-rod from the steam-chest, which should always be carefully packed; the sight-feed lubricator, which should be rigidly fixed; the prevention of the escape of steam; and regulation of the feed to a size no larger than a walnut. Frequently small cyanide plants are attached, costing £300 to £400, made of corrugated iron.

The following are the expenses for one month, exclusive of the owner’s time, the gold during that period being worth £303 4s. 9d., so a loss is shown in the month’s work:

The output of 112 tons crushed cost £3 3s. 4d. per ton.

A MODERN FUEL-OIL STORAGE SYSTEM.

Written for the Mining and Scientific Press

By H. W. Beecher.

At the 15,000-kw. steam-power central station recently installed at Redondo for the Pacific Light & Power Co., by the engineering firm of Charles C. Moore & Co., will be found a system of storage for fuel oil, which for reliability of service, as well as for safety, far surpasses anything to be found on the Pacific Coast. Not only is every contingency of operation provided against, but protection from fires and explosions is so well disposed of as to render impossible the repetition of the fire which occurred at this plant on January 27, 1908:

The general arrangement of the oil tanks is as follows: Oil is fed by gravity from the cars into a receiving tank, whence it is pumped into the main storage-tank, from which it is daily drawn into three auxiliary tanks. From these the oil is pumped through an oil-heater to the burners under the 18 Babcock & Wilcox water-tube boilers with which the plant is equipped.

As mentioned above, on January 27 a fire occurred in the auxiliary tank No. 1 which spread to the two remaining tanks, consuming about 2,000 bbl. of oil. These auxiliary tanks are of reinforced concrete, and are roofed over with a reinforced concrete cover or ceiling at the level of the boiler-room floor, to conform to the underwriters’ requirements. This roof ing is placed on I-beam supports, and is provided with a man-hole. In accordance with Charles C. Moore & Co.’s design this man-hole was to have been protected with a fire-proof cover, secured in place by staples, and padlocked. The doors into the boiler-room were to have been fire-proof. At the time of the fire, however, there were no permanent covers on the man-holes, nor were the doorways into the boiler-room provided with doors. The tanks were provided with smothering-pipes in accordance with the underwriters’ rules and specifications. These extend below the ceiling of the tanks, where they were left open-ended.

The use of a lantern in or around the oil tanks was contrary to orders, and smoking in the building was strictly forbidden by the Pacific Light & Power Co., which was particularly strict in this regard. In spite of all this, one of the men, on finding the fuses out on the lighting circuit attempted to measure the oil-level with a lighted lantern. An explosion ensued, igniting the oil in the tank. In an endeavor to smother the fire by turning on the steam from the smothering-pipes, the heated and burning gases were driven into the chamber above, causing a second explosion, demolishing the ceiling of the tank. The flames came through the doorways, ignited the other tanks, and did considerable damage in the boiler-room. While the fire was yet burning the Pacific Light & Power Co. place the matter of re-design in the hands of the engineering department of Chas. C. Moore & Co. Profiting by this experience, the fuel-oil tanks were re-built, and ample protective steps were taken in the reconstruction to ensure, first, a fire-proof system, and, second, an isolating arrangement,
whereby any fire would be confined to one tank. The chambers above the tanks, formed by the retaining walls, and running up a few feet above the grade-line, were open from one tank to another, before the fire. Brick partition-walls have now been put in, isolating these chambers one from another. These partitions are provided with fire-proof doors. A few feet above the grade-line there is a second or shelter-roofing. The brick partitions extend several feet above this roofing. The doorways into these chambers from the boiler-room have been bricked up so that no admittance can be gained except through fire-proof doors connected to the sump-hole. With this arrangement, should a fire occur, the damage would be confined entirely to one tank, and would in no way jeopardize the other tanks nor the operation of the plant. As a final precaution against a shutdown there is provided an independent connection of ample size for the operation of the plant at full capacity, whereby oil may be taken directly from the oil-storage tank. This oil line enters the building on the north side of the plant, and is entirely independent of the auxiliary tanks.

A few feet below the shelter-roof is suspended a ring of extra heavy 4-in. pipe, provided with numerous jets formed of 3/4-in. pipe, capped, and with a horizontal cut or slit across the cap. This ring is used in lieu of the usual smothering-pipes and serves as such. It is provided with the proper connections for bleeding in order to prevent water-hammer. When steam is turned into the 4-in. pipe, a sheet of steam is formed by reason of the fan-shaped jets, absolutely shutting off the air-supply and thus effectually smothering the fire. The cloud of steam, as well as serving as a blanket, by its rising action draws any stray air currents with it away from the fire, and drives them upward. This system of smothering is most modern, and supercedes the old arrangement of smothering-pipes, where there was a possibility of an explosion, and of the combustion of surrounding properties due to gases driven out of the tank by the steam, as on January 27, 1908. The control-valves of these smothering pipes are placed at a point easy of access from either the engine-room or the boiler-room, and is padlocked to prevent misuse.

For the purpose of measurement of oil burned, each tank is provided with a balanced float-measuring device, which shows the height of the oil in the tanks. This height is shown on two scales, one in the boiler-room, and one over the top of the tanks. With this system, accurate account is taken, and records kept, of the amount of oil burned during each six-hour period. Each tank is properly vented and provided with a supply-pipe, oil-pump suction with foot-valve and strainer, oil-return line, oil-circulating pump-return-line, steam to warming coils, and return from warming coils. The valves on these pipes are all placed on the boiler-room side of a concrete wall 3 ft. thick, between the boiler-room and the auxiliary tanks, this scheme making it unnecessary for any of the operatives to enter the chamber above the tanks for any purpose, and consequently doing away with the possibility of breaking the rules regarding lanterns, thereby lessening the fire-risk. This arrangement also insures the boiler-room operatives from danger, and permits the operation of all valves from the boiler-room during a fire.

When warming up an oil tank preparatory to the 'cutting-over' of the plant onto it, the oil-circulating pump is started. The oil-discharge line from this pump contains a thermometer-well together with a scale-case thermometer. In this way the boiler men can watch the oil-temperatures in their tanks without leaving the boiler-room. The suction line of oil-circulating pump is arranged with a swivel joint so that it can be raised or lowered. By pumping from the bottom of the tank, this pump can be and is used to discharge to the sump the entrained water which settles from the oil.

The complete control of the amount of oil, of the amount of steam for atomizing the oil, and of the air-supply, is automatically accomplished by means of a new system of regulation invented by J. R. Atchison and C. R. Weymouth. By use of this system the steam-pressure is kept uniform. At the same time, the most perfect conditions for combustion are maintained, irrespective of the load, namely, a constant automatic adjustment of steam to the burners and the air-supply, with the variation of oil-pressure. In this way the oil is properly atomized, and the right amount of air for combustion is furnished. This automatic system of regulation proved to be an important factor in the maintenance of the wonderful record made by this plant during the recent test. The testing committee's report states that the unparalleled average economy of 252.842 kw. hr. per barrel of oil burned was obtained during the 15 days' test. This economy was based on 18,500 B. T. U. per pound of oil, and 334 pounds of oil per barrel.

Detection of moisture, according to Bizt, may be made by taking advantage of the fact that 2KI.PbI₂ is colorless, but is partly dissociated by moisture, giving the yellow tinge of PbI₂. The re-agent may be prepared thus: A filtered warm solution of 4 gm. Pb(NO₃)₂ in 15 c.c. of water, is mixed with a warm solution of 15 gm. KI in 15 c.c. of water. PbI₂ first precipitates; on cooling the yellow color diminishes, until the mass becomes a network of interlocking white crystals of the double salt. After sucking as dry as possible on a filter, this is dissolved in 15 to 20 c.c. of acetone, which is filtered. The re-agent can be used in this state, or the salt may be precipitated out by adding double the volume of ether. The acetone solution may be used to impregnate filter paper, which slowly turns yellow from the moisture in the atmosphere (immediately if breathed upon). Such a paper may be used in many ways for the detection of minute amounts of moisture. Moistening with acetone restores the colorless condition.

Japan imported $13,754,000 worth of machinery during 1907, which is 49% more than in 1906, and 112% in excess of the average for the preceding five years.
CRUCIFORM STEEL FOR MACHINE-DRILLS.

Written for the Mining and Scientific Press
By E. F. Kennedy.

Drills for machines are commonly made by welding a piece of cruciform steel, approximately 14 in. long, to a bar of octagonal steel. The chuck-bushing of the machine-drill is ordinarily made either to receive round steel, in which case the octagonal steel has to be rounded for a length equal to the depth of the chuck-bushing, or the chuck-bushing is made to receive octagonal steel, and if one size of octagonal steel is used for all lengths of drills no blacksmith work has to be done on the shank-end of the bit. If two sizes of octagonal steel are used, the bushing can be made to receive the larger size, and the smaller size may be upset to fit the bushing: or, as is sometimes done, a short piece of the larger octagonal steel is welded to the end of the smaller octagonal steel.

There are some mines that use cruciform steel for the entire drill, and round down the shank-end to fit the chuck-bushing. This makes a weak steel, subject to breakage. The use of all cruciform steel, and chuck-bushings made to receive cruciform steel is, in so far as the writer knows, used in no other place for piston-drills than at the Treadwell mine, Alaska. There are many advantages in the use of all cruciform steel, some of which are: In drilling back-holes, which are slightly damped, with steel made by welding cruciform to octagonal steel, it is a common occurrence to lose a six or seven-foot hole by reason of the men not being able to get the steel out of the hole, and hours of time are often wasted in the attempt, whether successful or not. With the use of all cruciform steel, the ribs and grooves act much as a spiral conveyor to remove the dirt from the cutting-face, and there is no difficulty in removing the drill.

Each piece of welded steel costs about 50c. to make, which item is saved by the use of all cruciform steel. The use of a cruciform chuck-bushing obviates work on the shank-end of the steel, or almost does so. The practice at Treadwell is to use 1 1/2-in. cruciform steel for the first two drills, and 1 1/4-in. cruciform steel for the last two, four pieces of steel ordinarily making a set for the average depth of hole bored, which is 7 ft. The 1 1/4-in. cruciform steel is upset slightly to fit the bushing, which is made to receive 1 3/4-in. cruciform steel.

The change from welded steel to cruciform steel reduced the weight of steel in use in the Treadwell mine 16%. The cruciform shape making a more rigid and stronger bar than the octagonal or round steel. In the rough usage which steel gets in being thrown around, there is considerable breakage of the welded steel. The breakage occurs in the weak part of the steel, namely, near the weld. This is assuming that the welding is well done, which is not always the case. The use of the cruciform welding reduces greatly the breakage of the chuck-bolts, and the general wear and tear on the machine, and it lasts three times as long here as the octagonal bushing.

The common practice among machine men of running with a loose chuck-bolt to ream out a hole in order to allow another drill to follow is very expensive practice for the company supplying the machine extras. This 'running with a loose chuck,' as it is called, can be done with a round bushing, and also with an octagonal bushing, for the octagonal bushing is not in use long before it is reamed out practically round. With the cruciform bushing the piston cannot turn unless the drill does, and it is impossible to try to run with a loose chuck. When properly equipped there is little difference in the cost of making octagonal or cruciform bushings. At mines where machine drill-sharpeners are used for putting a cross-bit on an octagonal bar, no saving would be made in the blacksmith work by changing to cruciform steel, but they would gain by obtaining a stiffer stronger steel for the same weight by using cruciform steel, and thus would save in machine extras by using cruciform chuck-bushings. Where the ground is soft, and the wear and tear on the machines and steel is slight, there may be no appreciable advantage gained, but where the ground is stiff, and the consequent wear and tear on the machines and steel is heavy, the advantage in the use of all cruciform steel and cruciform chuck-bushings is apparent.

SILVER.

By Theo. F. van Wagener.

Previous to 1870 silver was reckoned as one of the precious metals, and possessed, by virtue of an unwritten agreement between the principal nations of the world, a definite value in terms of gold, namely, \$1.29 per fine ounce. The metal was never purchasable at less than this figure, and usually commanded a premium, which, during the last century, ranged from nothing up to as high as 10%. It is now purely a commodity, like all the other metals except gold, and while the demand has greatly increased since the date mentioned, the production has nearly quadrupled, and the price has fallen steadily until during last year it averaged 65e. Singularly enough, since this great change silver has become one of the three metals (nickel and copper being the other two) that circulate as coins at a valuation far above their commodity-price. This, of course, is due to the fact that they are by law legal tenders up to certain amounts, but the circumstance illustrates the vagaries of human laws when they come into conflict with those of nature. The American quarter, the English shilling, the Latin Union franc, the German mark, the Austrian kroner, the Russian rouble, all being coins that circulate freely at valuations ranging from 20 to 25e. of our money, would bring, if melted and sold as bullion, little more than half those figures. On the other hand, the Indian rupee, of approximately the same weight and fineness, not being backed by any such law, circulates at its commodity value only, and its purchasing power in the markets of the world fluctuates with the price of the metal.

Silver sometimes occurs in nature in the metallic condition, and it is due to this fact that it has been known from very ancient times. But it is not found, like gold, in grains or nuggets in the gravel of stream beds. Its principal habitat is the vein in rock, and hence it may be inferred that in antiquity the quantity possessed by man was much less than that of gold. To primitive man the latter metal was regarded, in a way, as a fragment, or at least as a representative, of the sun, while silver bore the same relation to the moon in his mind. When the interior of China becomes well known, it is likely that the remains of ancient silver mines will be found here, for the metal has been produced in that nation, in small quantity, from remote antiquity. There is no evidence that India ever possessed silver mines of note, but in Burmah have been found extensive slag dumps rich in lead and zinc, and carrying a notable percentage of the white metal. In the little known and rugged region between Hindustan, the Persian Gulf, and the Caspian Sea, embracing the erude nationalities known as Persia, Armenia, Afghanistan, and Beluchistan, there has been a small production of silver since early historic times, and the same may be said of Asia Minor. The Grecian peninsula, however, possessed a silver-producing region of great importance and high antiquity, from which, as early as 1000 B. C., the metal came in notable quantity. There are no known ancient silver-producing districts of note in Africa, but the Italian peninsula and Spain yielded the metal in early historic times, the former moderately and the latter very abundantly. In fact, Spain was really the first great silver-mining country of the world.

More than any other metal, silver has been intimately associated with the advance of civilization, or rather, of that very important department of human activity that is called commerce, meaning thereby international trade. Authentic history seems to begin with the fact of two comparatively peaceful, industrious, and frugal races, occupying the rich valleys of the regions now called India and China; and a lot of turbulent, migratory people in western Asia, eastern Europe, and northern Africa, who devoted much of their time and energy to fighting and destroying each other’s homes. Between the two was the highest and most difficultly passable mountain chain in the world, known now as the Hindoo Koosh and Himalaya range, which for centuries, and perhaps millennia’s, kept them apart effectively enough to allow each to develop its own peculiarities. The first, whom we distinguish as Orientals, appear to have settled down at an early period to agricultural pursuits, and to such peaceful arts and occupations as were naturally the outgrowth of rurality. Population grew, a crude and quiet, yet strong trading capacity developed, religious advance was marked. It was not of the proselyting kind, but was rather contemplative and introspective. The arts progressed only to a certain point, and then became stationary. Wealth was attained by industry and accumulation mainly, and did not often arise from exploration or conquest. Such luxury and ease as resulted never passed far beyond the barbaric stage. The sciences did not become exact or even organized, and they have retained, even to the present day, an air of mysticism.

The second, whom we may call the Occidentals, advanced along wholly different lines. Every department of life was more strenuous. The increase of population was perhaps as great, but the destruction of life by wars and through slavery was enormous. The arts flourished, but their product was continually being looted by conquerors. This ruthless destruction, however, seems to have incited rather than discouraged improvement.

Between these diverse and different kinds of humanity a trade slowly sprang into existence. It was first, doubtless, by way of the Arabian Sea, which at some time in the distant past was a mare clausum, a Mediterranean. The Western nations sought the luxuriant and decorative products of the Eastern, their fabrics of silk and wool, their manufactures of bronze, their gems and jewelry of ivory and jade. What could be given in exchange? The money of the East was silver, it was scarce there, and its purchasing power was great. Consequently when the strenuous West began to produce the metal in quantity, first from the mountains of Persia and Asia Minor, and later in Greece, Italy, and Spain, it became possessed of an article with which the products...
of the East could be obtained. But the West loved war above other things, and had the warrior’s immemorial contempt for trade. So when there grew up at the extreme eastern end of the Mediterranean, a nation of traders, the Phoenicians, they promptly took charge of the commerce between the Occident and the Orient. For centuries the Phoenicians were actually protected in turn by all the great powers of antiquity because of their trading ability, and their knowledge of where and how to get the products of Asia that Europe wanted. We know that the ships of Tyre and Sidon ransacked the shores of the Mediterranean for silver, and were the owners and operators of mines of that metal in Greece, in Italy, and in Spain. Their product was sent overland by caravans or oversea by ships sailing from ports on the Persian Gulf, and later from ports on the Red Sea, to India, to be exchanged for the goods of the East. One of the most valued of these was tin. Malaysia has been from the most remote antiquity, and is today, a prolific producer of this metal, and early in the history of the human race the extremely desirable qualities of the alloy (bronze) which it made with copper became known. For many centuries primitive Europe poured its silver into Asia and sold it for tin. In due time the demand became greater than the supply. At the same time the product of the European silver mines began to fall off. The price of tin in terms of silver increased greatly. So also did the value of silver. In this crisis, which threatened the very existence of trade between the East and the West, two remedies were tried. The Greeks, the dominant nation of the time, under Alexander the Great, started out to conquer India, and to find and capture the Asian tin mines, but, as we know, he got no farther than the Indus. Simultaneously the Phoenicians, in their search of the western world, found tin in Britain. When Cornish tin began to come into the market, the ‘corner’ that Asia had for so many centuries maintained on tin was broken, the Malay suns fell rapidly into decadence, and the ancient value of silver in the East was resumed. Europe then had the advantage, but as its silver product was declining, its trade with India fell away, and the two far-separated dominant peoples of the world almost forgot each other. Europe, now well supplied with tin and copper, devoted itself to strenuous war and destruction. A thousand years or more later, when the Roman Empire had passed its prime, new silver mines were found in central Europe, and again trade with the East began to revive. Venice was then the commercial centre of the world, and it flourished as long as the Austrian and German silver mines were in bonanza. When the cream of these was skimmed it began to decline. From that day until the Spanish galleons began to bring silver from the New World, times were hard in Europe, civilization languished, and humanity suffered. Historians call the period the ‘Dark Ages.’ History also records the wonderful change that took place when the Mexican and Peruvian silver mines began to pour their flood of treasure into Europe. There was a marvelous revival of industry, and of the arts and sciences, and the greater part of it was directly due to the enormous coinage of Mexican silver dollars, and their wide distribution in trade. This coin for three centuries has had a larger circulation, and has become more extensively known, than any other tangible product of the hand of man.

From the discovery of America to about the beginning of last century, the source of the world’s supply of silver was almost entirely the mines of Mexico and the west coast of South America. The production in this period is estimated by statisticians at nearly 200,000 tons, and its value (then about $30,000 per ton), at $6,000,000,000. The bulk of this vast total went first to Europe, more than half of it in the shape of coins of American mintage. The remainder went into European coinage and plate. This great store of what was, in those days, a money-metal of unlimited legal-tender value, enabled the New World to buy what it needed of Europe, and permitted the latter to resume its trade with the Far East. Spain, practically the parent and owner of those regions whence the metal came, prospered prodigiously, and became the wealthiest of the nations. But in 1810 its colonies began their struggle for independence. Spain resisted, and begged for itself the effort to retain them. The contest lasted more than a decade, and during it the silver-mining industry suffered greatly. In South America it was almost suspended. The supply of the metal in Europe for coinage became scant, the trade with the Orient again declined. In the middle of this period, when the destructive career of Napoleon was coming to an end, when all Europe was in financial distress, and vast amounts of plate had gone to the melting pot to be transformed into coin, with silver advancing in value (in terms of gold) until it commanded the equivalent of $1.40 to $1.45 per fine ounce, with the coinage of some of the nations in process of debasement by the addition to the alloy of lead and tin. England, in 1816, established the mono-metallic gold basis, and started the train of conditions that later (in 1873) resulted in the complete demonetization of the white metal. And in this connection it is a curious fact of history that while England in 1816 abandoned silver as a money-metal because of its scarcity and high relative value in terms of gold, the rest of the great commercial nations followed her footsteps nearly fifty years later because of its abundance and falling value.

When Mexico became independent, in 1821, it passed into a condition of anarchy that lasted almost a half-century. In this period its mines were operated under the greatest disadvantages, and the amount of silver exported was comparatively small. But as soon as political affairs became settled, under President Diaz, the mining industry began to revive, and today the Mexican output of the white metal exceeds that of any other nation. Previous to 1859, when silver was first discovered in the United States (in Nevada), silver mining was not an organized industry, but an occupation dependent largely for success upon the accidental discovery of bonanzas of rich ore, coupled with the ability to secure labor upon a basis of practical slavery. Only one step on the road of progress had been taken in the metal-
lurgy of the metal, namely, the invention of what is known as the ‘patio process.’ But when it became evident that the Comstock Lode, in Nevada, contained vast quantities of silver, the natural ingenuity and aptitude of the American transformed mining into a commercial industry, and the metal began to pour in such torrents into the money centres of the world that financiers became alarmed, and between 1870 and 1873 full coinage-rights were denied by the principal nations. Meantime, a remarkable industry had come into existence in the mountain regions of the West. Thousands of silver mines had been discovered, scores of processes put into practice for the treatment of their ores, and a vast number of metaliferous deposits developed that have since been yielding copper, lead, zinc, iron, and manganese, in addition to the white metal.

Silver occurs in veins or deposits in the rocky crust of the earth, and is never found in the gravel of stream-beds, as is gold. In a small number of cases the gangue, or material with which the metal is associated, is quartz alone, but generally one or more of the base metals is present, predominating vastly in quantity, and often in value. This is especially true after a little depth is gained on the veins, so that in due time mines that were opened as straight silver-deposits become deposits of the other metals, the silver being practically a by-product. A good example of this change is to be found in the lodes at Butte, Montana. The veins at Parral, Pachuca, and Guanajuato, in Mexico, are examples of straight silver mines, yet all of them are showing more or less associated iron or copper as depth is gained. On the other hand, wherever lead is found, silver is always present in some quantity, and at the Comstock, as well as at the Mexican districts mentioned, there is invariably a proportion of gold. In the Comstock bullion it amounted to 40% of the total value. Thus the metallurgy of silver is not a simple matter, and between 1860 and 1873, when the metal had a value of about $1.30 per ounce, a vast amount of study and experiment was devoted to the question of recovering it from its ores by milling processes, or methods not involving the fusion of the minerals. But as the West became opened by railroads, so that ores could be cheaply transported to natural centres, where coal or water-power existed, and where labor was abundant and inexpensive, most of these processes were abandoned in favor of smelting. In consequence, the production of silver may now be considered as a settled industry, the metal being produced largely as a by-product.

Since its discovery in the United States the world’s output has amounted to nearly 170,000 tons. There has been nothing comparable to this enormous yield in any previous era of history, and its fall in value may be considered as warranted, and perhaps permanent. The annual output of the world at the present time averages about 6000 tons, and is not at all likely to seriously decline. The American and Mexican mines show no signs of exhaustion. On the contrary, new mines are continually being discovered. Asia and Europe are not likely to become large producers of the metal. The settled parts of the Old World have been fairly well explored, and in the unsettled parts like Siberia, Turkey, and Africa, the mining laws are so burdensome that the prospector and individual miner will have nothing to do with those regions. We may, however, confidently look to South America for many new and great silver mines, when the political situation becomes as stable as it is in Mexico, for Spanish mining law has always recognized the necessity of the prospector at the base of the industry. The extent to which the American crop of silver is a by-product is shown by the following table, worked out by myself, for the year 1899, when the product of the mines of the United States amounted to about 2100 tons:

<table>

In Mexico, on account of the activity at Parral, Pachuca, and Guanajuato, the proportion of silver coming from silver ores is larger, and perhaps the same is true for South America. But in Europe, Asia, and Africa practically the entire product of silver comes from the lead and copper mines, so that for the entire world the proportions quoted in the above table would be about correct. The demand for the metal is growing, and may be expected to increase markedly in the near future. The largest consumers now, as in the past, are the three great backward races of the Far East, the Hindus, the Malays, and the Chinese. It takes from 2500 to 3000 tons every year at present to maintain trade with them, and but one, the people of Hindustan and Farther India, may be said to have more than wakened from their sleep of centuries. These number about three hundred millions of frugal, industrious, acquisitive people. When the four hundred million of Chinamen are thoroughly aroused, and the one hundred million of mixed races that include the Filipinos and the inhabitants of the East Indian islands, there will come at least as large a call for the metal as that which now exists. For silver is the only money that the Orient recognizes, or will use. The capacity of that part of the world for absorbing it has always been the wonder of economists, to whom Asia is known as the sink of silver.’ Statistics show that an average of not less than 600 tons of the metal has been sent to the East by Europe annually during the last 300 years. Practically none of it has ever come back. Among the thousand million Asiatics it has disappeared, being absorbed in hoards of coin, or bars, or used as ornaments, or circulated as money. This curious process is in progress today with nearly five-fold the vigor of the past. Practically 79% of all the silver produced in Europe and America since the dawn of history is now in the possession of the Chinese, Japanese, Malays, and Hindus. Yet we regard them as a poverty-stricken people, which in fact they are, for with all this immense hoard of what was once the paramount money-metal of the world, famine or pestilence is abroad nearly every year in one or more parts of the Orient. This vast metallic accumulation
will not save them when crops fail and starvation is at hand, for the West, having demonetized silver, will not accept it in exchange for food except on the basis of a pure commodity.

From 400 to 500 tons of the metal is at present being consumed by the world in manufactures and the arts. Such parts as are used in photography and by the chemist may be regarded as lost, which amount to as much as 50 tons per year. The balance becomes tableware, jewelry, and ornaments. About 5000 tons goes into coining, 50% of which is minted in Asia, approximately 25% in Europe, 15% in Mexico and South America, and the rest in the United States. All this, except the coining of India, Mexico, and Japan, is bought by the various governments at the commodity-value of the metal, and after taking the stamp of the mint it goes to the public on the basis of the old ratio of 16 to 1, compared with gold. The difference is absorbed as profit, under the name of seigniorage. This profit to the treasuries of the civilized nations now amounts to something over $10,000,000 per annum, and is somewhat of the nature of a fraud on the people, though with the existing conventions in the matter of money and coining, it is not easy to say how the fraud is to be avoided.

Considered wholly by itself, and from the standpoint of its purely physical properties, silver is yet a precious metal. Its pure white color and soft lustre can not be approached in aluminum, tin, nickel, or any other metal, and though it tarnishes quickly, and has not the resistant qualities of gold to the action of acids and of sulphur, yet no metal we at present know can take its place for small coining, or for ordinary tableware and decorative purposes. Aside from these uses, it is the best conductor of electricity of all known substances, and there may be a special future for it in the wonderful development of that new servant of man. Perhaps as the science of wireless telegraphy and telephony advances, silver may come to be employed in the reproduction of sound waves when great distances must be bridged, or extreme delicacy of enunciation is desired. Yet copper approaches it so closely in electric sensitiveness, and is so much more abundant and cheaper that we may not look forward to talking in future over silver wires.

The world’s crop of silver during 1907 amounted to about 6400 tons, and came from the following parts of the globe in the quantities given:

<table>

</table>

From these figures it appears that nearly 80% of the annual product is coming from the western hemisphere, and if we add to this the output of Australiasia, the proportion coming from what may be regarded as the newer parts of the world, rises to 85%. Finally, by including the European product, it appears that Asia, where the metal is most in demand, and where it still retains its old debt-paying quality, produces less than 3% of the world’s crop. Hence there is still a large field for silver in the Orient, and its exploitation and development is undoubtedly the next great task of the Caucasian. In this view the silver miner may take some comfort.

**NEW THEORY OF BAND ORE DEPOSITION.**

The excellent assay-values disclosed by the developments in the Main Reef West, and the encouraging results obtained in the Vogel Deep, both of which mines are situated to the south of that exceedingly poor strip of outcrop which stretches from Langlaagte to the Durban Roodepoort, have suggested a new theory for the distribution of gold in the Witwatersrand belt. It is well known that the rich zone in which the outcrop and first row of deep-level mines of the central section are situated, does not, so far as revealed by present developments, extend into the deep-deeps of that vicinity. Having regard for the demonstrated fact that the Witwatersrand as a whole shows a remarkable uniformity of mineralization, and that comparatively rich patches are not confined to any one section, but are dotted over the whole length of the field, it would not be unreasonable to expect that the assay-values on the dip of an exceedingly poor outcrop would show a considerable improvement; indeed, the balance of probability actually points to that being the ease. The theory in question, however, goes even further than that. It is to the effect that the rich central outcrop belt, instead of ending at Langlaagte, as commonly supposed, continues westward, and takes an inclined course on the dip, instead of clinging to the outcrop. This view is, of course, by no means in conflict with the known laws of ore deposition. The theory is, we believe, only put forward tentatively, until such time as the necessary data, in the shape of the assay plans of the developed mines in that portion of the Reef, have been examined. Many instances may be recalled where the outcrop is vastly better than the adjoining deep-levels. The stopes of the Jumpers mine, for instance, never fell below 10 dwt., while those of the Jumpers Deep never reached that figure. It is true that the two are separated for a great deal of this length by a longitudinal dike, but the balance of opinion today is that the dikes have no influence on the gold content. It is a matter, however, that cannot be said to be settled. Another explanation to account for the difference in outcrop and dip that has long been in favor is that the gold runs in northeast and southwest shoots. As we pointed out in a recent article, the gold in the Main Reef of the Jumpers mine undoubtedly occurred in shoots, and these shoots trended more or less in that direction. Another factor that introduces complications in endeavoring to arrive at a solution of this and allied problems, is the undoubted secondary enrichment that has taken place in the outcrop mines.—*South African Mining Journal.*
THE GRANADENA MINES.

Written for the Mining and Scientific Press
By S. F. Shaw.

The mines of the Granadaña Mining Co. are situated in the Hidalgo mining district, about three miles northeast of Santa Barbara, Chihuahua, Mexico. The ores are a complex mixture of galena, sphalerite, chalcopyrite, and pyrite, carrying varying quantities of gold and silver. In the early days of mining in the district considerable quantities of high-grade ore, consisting of 30 to 60% lead in the form of lead sulphide, carbonate, and sulphate, and various oxidized lead compounds high in silver, and in some cases in gold, were taken from workings at or near the surface. In the very early days extraordinarily high-grade gold ore was taken from the famous San Francisco del Oro mine, from the Tesolote mine, and from others near by.

These high-grade surface deposits have been largely worked out, and the greater part of the mining is confined to extracting the ore from the larger lower-grade orebodies. The principal veins being worked by the Granadaña Co. are the Granadaña, Mereed, Graencia, Guadalupe, and San Luis. Many other veins traverse the property, some of which have been opened up to a small extent, while others have not yet so much as had a pick driven into them. The country rock is a close-textured shaly limestone with the veins traversing it in all directions. The geology has not yet been worked out, and it is not known which veins, if any, were the earliest. The dip of the veins, however, is fairly uniform, being usually about 70 degrees.

The greater amount of work has been done on the Granadaña vein, which is worked from two shafts, one inclined and one vertical. The inclined shaft is on a slope of 70°, and lies in the vein to a depth of 150 ft., where it runs into the country rock, owing to the vein dipping slightly more than 70° at this point. The total depth of this shaft is 370 ft. Five levels have been turned off, all of which are in the orebody that has been up to the present time developed. A total of about 4200 ft. of work has been done on this vein.

Until a year ago the ore was mined by both overhand and underhand stoping, and was very expensive. Underhand work was then stopped, and the levels so arranged that all the stoping would be done by underhand work. Stulls were set across the levels about 6½ ft. above the rail, and a lagging of slabs from 2 to 4 in. thick was laid across these stulls. The ore was then allowed to drop on this floor, and only enough drawn off through the chutes to allow room for the miners to work on the top of the broken ore. Hand-drilling was replaced by small air-hammer drills. These changes made a notable saving in the cost of mining. The ore is hoisted in buckets of about ½ ton capacity by a small friction hoist.

Air for the Granadaña and Mereed mines is supplied by a 14 by 12-in. two-stage Norwalk compressor and an 11 by 17 by 16 by 10 by 12-in. cross-compound two-stage Laidlaw-Dunn-Gordon compressor. A No. 9B Cameron sinking-pump throws the water from the sump at the bottom of the shaft to the fourth level, from which it is raised to the surface by a 7 by 4 by 10-in. Smith-Valle duplex pump. A 7 by 4 by 10-in. Smith-Valle duplex pump then throws the water through a 3-in. pipe-line to the mill reservoir. The vertical shaft is 310 ft. deep, and when extended in depth it will penetrate the vein at an estimated distance of 1000 ft. It is now connected with the fourth level. The ore is hoisted through this shaft by an 8½ by 10-in. double-drum geared Ottoman hoisting-engine. From both inclined and vertical shafts the ore goes to sorting-bins, where the waste and a certain amount of shipping-ore are sorted out, the remainder going by surface-tram to the mill, a distance of about 1700 ft. A battery of four boilers, aggregating 280 hp., supplies the hoisting-engines and compressors with steam. The ore is largely oxidized to a depth of about 75 ft. At about 50 ft. there is a zone of gold-enrichment, from which point a considerable quantity of screened ore has been shipped, averaging about 1 oz. gold, 12 oz. silver, and 10% lead. Below this point occurs a zone of mixed oxidized and sulphide ore averaging 0.6 oz. gold, 9.5 oz. silver, and 10.5% lead. After the oxidized zone is completely passed, the ore averages 0.2 oz. gold, 7 oz. silver, and 10% lead.

The Mereed vein is opened by an adit driven along the vein a distance of 1400 ft. The inclination is 70° from the horizontal, and the strike has a general northwest-southeast trend. The average width is 6 ft. The greatest depth reached by this adit is 160 ft., but as the vein at the breast turns somewhat more into the mountain, the continuation will give greater depth than this. Two shafts connect with the surface, and three winzes are below the adit to a depth of 1000 ft. or more each. To a depth of 100 ft. below the adit the ore is either entirely oxidized or is oxidized, with stringers of galena varying from a fraction of an inch to a foot in width running through it. Specimens can be picked out at nearly any point showing the stage of transition passing from galena through anglesite to cersusite. No. 3 winze, at a distance of 1000 ft. from the portal of the adit, is being made the main working-shaft for extracting the ore below the adit-level. It is 16 ft. wide and equipped with a 6½ by 8-in. single-drum Ottoman hoist and a 50-gal. Cameron differential pump. This winze passes through the body of ore which careful sampling has shown to average 0.4 oz. gold, 18.5 oz. silver, and 34% lead. No. 2 winze is 140 ft. deep and is equipped with a 5 by 6-in. winze-hoist. Shipping ore is now being extracted from these two winzes. At a depth of 120 ft. below the adit the present water-level is found, and this is apparently the point at which the permanent sulphide-zone is reached.

The ore in the Mereed mine is broken down entirely by overhand stoping, and is trammed to a 350-ton sorting-bin, from which point a single-bucket aerial tramway, with a span of 750 ft., conveys the milling ore to the mill-bin. A rich lead shipping product is sorted out, and from time to time a few tons of copper ore is also shipped. This is the only vein on the
property being worked at present. Development is being continued, and a few cars of very good shipping ore are being produced every week.

All development is done by Mexicans on a contract basis, varying from P20 per metre in the soft vein rock to P40 per metre in the hardest rock. The average price is about P25. The price paid for sinking is about P5 more than for driving. Powder, fuse, and caps are furnished to the contractors by the Company at cost price.

The mill was closed down on February 1, due to the drop in price of lead and silver, and has not yet resumed operation. It has a capacity of 225 tons per 24 hr. The ore delivered to the mill is treated as follows:

1. Mill-bin, 200 tons capacity, to (2).
2. Inclined grizzly, slope 45°, fines to (4), oversize to (3).
3. 10 by 16-in. Blake crusher, through 1½-in. ring, to (4).
4. Storage-bin, 800 tons capacity, by plunger-feeder to (5).
5. 16 by 36-in. C. I. W. rolls set ½ in. apart to (6).
6. Elevator to (7).
7. Hexagonal trommel with ½-in. round-punched openings, undersize to (9), oversize to (8).
8. 14 by 27-in. Davis rolls set ¾ in. apart to (6).
9. C. I. W. impact screen, 10-mm. openings, oversize to (15), undersize to (10).
10. C. I. W. impact screen, 5-mm. openings, oversize to (6), undersize to (11).
11. C. I. W. impact screen, 2-mm. openings, oversize to (17), undersize to (12).
12. C. I. W. impact screen, 1-mm. openings, oversize to (18), undersize to (13).
13. No. 1 Richards hydraulic classifier, overflow to (25), overflow to (14).
14. No. 2 Richards hydraulic classifier, overflow to (26), overflow to (29).
15. No. 1 jig, first side-discharge to (42), first hutch to (43), second, third, and fourth side-discharges and hutches to (19), tailing to (27).
16. No. 2 jig, first side-discharge and hutch to (42), second, third, and fourth side-discharges and hutches to (19), tailing to (27).
17. No. 3 jig, first side-discharge and hutch to (42), second side-discharge and hutch to (43), third and fourth side-discharge and hutches to (20), tailing to (27).
18. No. 4 jig, first side-discharge and hutch to (30), second side-discharge and hutch to (42), third and fourth side-discharges and hutches to (30), tailing to (27).
19. Elevator to (8).
20. 12 by 20-in. Davis rolls set close together, to (21).
21. Elevator to (22).
22. Trommel, 2-mm. wire screen, oversize to (20) or (30), undersize to (23).
23. Trommel, 1-mm. openings, oversize to (24), undersize to (13).
24. No. 5 and 6 jigs, first hutch to (42), second hutch to (43), third and fourth hutches to (30), tailing to (46).
25. No. 7 jig, first hutch to (42), second hutch to (43), third and fourth hutches to (30), tailing to (46).
26. No. 8 jig, first hutch to (43), second hutch to (43), third and fourth hutches to (31), tailing to (46).
27. De-waterer, 10-mesh screen, oversize to dump, undersize to (28).
28. Sand-box, spigot product to dump, overflow to (29).
29. Cailow cone settling-tank, spigot product to (30), overflow to (46).
30. 5-ft. Bryan mill, through 10-mesh screen to (31).
31. No. 3 Richards hydraulic classifier, spigot product to (35), overflow to (32).
32. No. 4 Richards hydraulic classifier, spigot product to (36), overflow to (33).
(33) No. 5 Richards hydraulic classifier, spigot product to (37), overflow to (34).
(34) Box classifier, spigot product to (38), overflow to (39).
(35) No. 1 Wilfley table, concentrate to (43), middling to (40), overflow to (39), tailing to (46).
(36) No. 2 Wilfley table, concentrate to (43), middling to (40), overflow to (39), tailing to (46).
(37) No. 3 Wilfley table, concentrate to (43), middling to (40), overflow to (39), tailing to (46).
(38) No. 4 Wilfley table, concentrate to (43), middling to (39), overflow to (46).
(39) Callow cone settling-tank, overflow to (46), spigot product to (41).
(40) No. 5 Wilfley table, concentrate to (43), tailing to (46).
(41) Two 6-ft. Frue vanners, concentrate to (43), tailing to (45).
(42) First-class concentrate-bin, concentrate to smelter, overflow to (44).
(43) Second-class concentrate-bin, concentrate to smelter, overflow to (44).
(44) Two galvanized-iron settling-tanks, concentrate to smelter, overflow to (45).
(45) One Callow settling-tank, overflow to (48), spigot product to dump.
(46) One 11-ft. settling-tank, overflow to (47), spigot product to dump.
(47) Two 11-ft. settling-tanks in parallel, overflow to (48), spigot product to dump.
(48) One 11-ft. sump-tank, to (49).
(49) Pumped by No. 4 Traylor two-stage centrifugal pump to (50).
(50) 33,000-gal. reservoir at top of mill.

The tables and vanners are run by a 7 by 10-in. Erie single-cylinder slide-valve engine at 180 r.p.m., which also drives an 11-kw. General Electric Co.'s dynamo. The rest of the machinery is operated by a 12 by 36-in. Bates-Corliess single-cylinder engine, running at 96 r.p.m. Two 100-hp. boilers supply steam for the engines and pumps.

Owing to the sulphides being so intimately associated, it is impossible to secure a high percentage of extraction, and to secure high-grade concentrate a very serious loss is inevitable. In treating the oxidized ores a great loss is sustained from excessive dissolving out of the sulphates and carbonates.

The following percentages of extraction show the low degree of saving made on these ores:

These figures of extraction are based upon smelter returns, which, including losses in transmission, are about 5% lower than if based on actual mill returns. This concentrate nets from the smelter about $5 U. S. currency per ton of ore as taken from the mine, which is very low compared with the total value of the metals in the ore, which at present prices as quoted in New York is about $30 U. S. currency. The ores of the Santa Barbara district will average between $20 and $30, and as the above figures on extraction are as good or better than those usually obtained, it is readily seen that the present method of wet concentration, followed by smelting, is altogether unsuited for this class of ore. Many different methods of concentration have been and are being tried, including magnetic separation, electrostatic separation, flotation processes, processes of dry concentration, and so on, but none is thoroughly successful. Since the sulphides are so intimately associated, fine grinding is necessary to release the different minerals, which is attended by an excessive amount of dust or slime, which it is impossible to treat economically. There are many hundred thousand tons of ore of this character in this district which lie awaiting a successful method of treatment, which must, in my opinion, be worked out along a chemical line of treatment, involving leaching, or fusion, or both.

**TIN IN THE UNITED STATES IN 1907.**

The United States uses from 40,000 to 50,000 tons of tin annually, or between 35 and 40% of the world's production, yet the supply is practically all imported from foreign countries, and in addition to the pig tin there are large importations of tin-plate, sheets of either iron or steel coated with tin. The American tin-plate industry has grown enormously during the last 15 years, but the production of tin, the metal, has been a negligible quantity. Last year it was but about one-twentieth of one per cent of the world's total production. In an advance chapter of Mineral Resources of the United States, Frank L. Hess, of the U. S. Geological Survey, discusses the waste of the metal with reference to the world's small visible supply. He says: "The recovery of tin from scrap, dross, type metal, babbitt and other antifriction-metals, bronze, and the like, is growing. The amount of tin wasted in tin cans that have been used and thrown away, and in the solder used on them, is very great, and is an extravagance which, from a broad economic view, is deplorable. Although the amount of tin ores to be drawn upon cannot be as accurately measured as the coal deposits of the world, their exhaustion seems as certain, and unless some new unrecognized substitute for tin is found, such as an economical method for the production of aluminum from clay might give, such saving will become compulsory. During the year 16 companies in the United States recovered tin amounting to 1662 short tons, valued at $914,404, while a large recovery of tin from secondary sources was also made in Europe.

In a new iron-making process, recently developed in Stockholm, the ore, coal, and other materials are finely pulverized and drawn into the furnace in a continuous stream by means of a current of air or carbonic oxide. The furnace is a vertical cylinder, with a tap-hole for the iron and an escape-hole for the gas near the base. The coal is burned to carbonic oxide in the upper part of the furnace, and the slag and reduced iron collect on the furnace-wall and flow down to the lower end.

An ore-jigger comprising a tank, and sieve movable upward and downward in the tank, levers pivoted at their outer ends and extending inwardly over the sieve, rods connected with the levers and extending upwardly therefrom, springs on said rods, eccentrics, straps on said eccentrics and having rods connected with the inner ends of said levers, the levers being provided near their pivoted ends with vertical openings, hangers connected at their lower ends with the sieve and extending upwardly through the openings in the levers and having slots within the openings or slots of the levers, pins passing through the slots in the hangers and connected with their respective levers, springs on the upward extension of the hangers and bearing between the levers and abutments on the said upward extension of the hangers and a carrier operating between the levers and the sieve, all substantially as and for the purpose as set forth.

PROCESS OF EXTRACTING METALS FROM ORES.—No. 896,245. James H. Reid, Newark, New Jersey.

The herein described process of extracting metals from ores, which consists in successively subjecting the ore in vacuum to a series of different heating operations and condensing separately and independently the metals sublimed in each.

In a rock-drill, in combination, a pair of boring tools, means for rotating said tools intermittently, hammers for striking said tools alternately, connections adapted to operate by air under pressure for moving said hammer, valves for controlling said connections, and lever devices for controlling the operation of the valves and the operation of the tool-rotating means.
Decisions Relating to Mining.

Specially reported for the Mining and Scientific Press.

**MINING CLAIM—LOCATION AND DISCOVERY BY AGENT.**

A mining claim may be located by an agent, even without the knowledge of the principal. So where a person entered on land and performed the acts necessary for a valid location of a placer oil-claim, except making a discovery of minerals, but before any discovery thereon, sold a part of such claim to another, and then abandoned the other part, and thereafter entered the employment of a third person for the purpose of locating placer oil-claims, and then entered on the same land as agent for such third person, and completed a valid location thereon by making a discovery, such discovery inured to the benefit of such third person; and the fact that such agent had previously made a location on that part of the claim for himself, except discovery, and had conveyed what interest he had in the claim to such original grantee before entering the employment of his principal, did not affect the right of his principal to the benefit of his discovery and location.

Whiting v. Straup, (Wyo.) 95 Pac. 849, May, '98.

**EXTENT OF PLACER CLAIM—DISCOVERY.**

A placer claim is limited to 20 acres for each individual locator, and the aggregate that may be located as one claim by an association of persons is limited to 150 acres. However, when more than 20 acres is located as one claim, one discovery is sufficient for the entire claim, and when a valid location is made, a legal right of possession follows.

Whiting v. Straup, (Wyo.) 95 Pac. 849, May, '98.

**CORPORATION PURCHASING ITS OWN STOCK.**

A mining corporation in Arizona was held to have the right to take from its own stock, where such purchase was made in the discretion of the officers in good faith, and in the exercise of their control of the affairs of the corporation, for the purpose of getting rid of the superintendents, whose management was thought to be injurious, and where the corporation was solvent. In the absence of statutory prohibition, a corporation may purchase its own stock; the validity of the transaction will usually depend upon the circumstances of the case.

**RIGHT OF MORTGAGEE TO PERFORM ASSESSMENT WORK.**

Where a mortgage on several mining claims required the mortgagee to perform the annual assessment work, and provided that on failure to do so the mortgagee, if he deemed it necessary, might do such work, and the expenditure therefor should be a further lien on the claims, the mortgage was held to be within his rights in performing assessment work on such claims as the mortgagee failed to work upon. The fact that the mortgagee performed a large amount of work upon one of the claims was not sufficient to compel the mortgagee to accept such work as done for the benefit of all the claims, and thereby risk the chance of an adverse determination of the question as to the sufficiency of such work for all the claims.

Copper Bell Min. Co. v. Costello, (Ariz.) 95 Pac. 94, March, '98.

**MINING CLAIM—POSSESSION.**

Where actual possession was not taken by a purchaser under a contract to purchase mining claims not described by metes and bounds, such purchaser was not in constructive possession of the ground claimed by the vendor under his original location, and not included within the patents to the claims, for the reason that a person cannot be constructively in possession of property not falling within the description of some muniment of title held by him.

Butters Filter at Salvador.

The following letter from James S. Colbath to H. P. Garthwaite, of the Butters Salvador Mines, Ltd., gives details of great interest concerning the operation of the cyanide filter-plant at San Sebastian, Salvador:

**Butters Salvador Mines, Ltd.**

**San Sebastian, July 15, 1908.**

H. P. Garthwaite, Esq.,

**Resident Director.**

Butters Salvador Mines, Ltd.

**RE-OPERATION OF BUTTERS FILTERS AT SAN SEBASTIAN.**

"Dear Sir:—The filter is a model of convenience and, working on this slime, gives extraordinary results as compared with other installations that have come under my observation. The most remarkable of these results is the capacity, due largely to the porous nature of the calcined slime. The cycle of operations for each charge of 7 tons of dry slime takes one hour and twenty minutes. Allowing for washing down, our present output of about 28 tons can be handled in 6 hours; or, making still further allowances, 100 tons can quite easily be handled in 24 hr. I doubt if this has been equaled with a 36 leaf filter. The cycle of operations is as follows:

<table>
<thead>
<tr>
<th>Operation</th>
<th>Min.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Filling with pulp</td>
<td>5</td>
</tr>
<tr>
<td>Forming cake</td>
<td>7</td>
</tr>
<tr>
<td>Returning pulp</td>
<td>5</td>
</tr>
<tr>
<td>Filling with solution</td>
<td>3</td>
</tr>
<tr>
<td>Washing with solution</td>
<td>2</td>
</tr>
<tr>
<td>Returning solution</td>
<td>5</td>
</tr>
<tr>
<td>Filling with water</td>
<td>5</td>
</tr>
<tr>
<td>Washing with water</td>
<td>5</td>
</tr>
<tr>
<td>Dropping cakes, draining water, and discharging, from 10 to 15</td>
<td>1 hr. 20 min.</td>
</tr>
</tbody>
</table>

This is not a trial run, but what we are doing four or five times a day, and at this time between charges. Anyone familiar with the vacuum filter will note the short time necessary to form the cakes, and the short washing period. The first could be still further reduced, by having a thicker pulp, to 5 minutes or less. The specific gravity is purposely kept below 1.29 to avoid "freezing" cakes.

The washing period is limited by the amount of solution that can be used on the plant without precipitating copper. The quantity passing through the filter is from 3 to 3 1/2 tons per day of dry slime, which is, I believe, two or three times the normal quantity. The solution in the pulp assays from $15 to $20, and the residue shows from nothing up to 10c. soluble gold. The slime is given but one treatment, and the solution contains in addition to the gold dissolved from the slime, that dissolved in the pulping amounting to 2.5 to 3 oz. per ton of dry slime. To pass this directly to the filter without dilution, and reducing soluble gold to less than 10c. is certainly good work. The slime residue averages $1, and on the basis of the above figures, the extraction approximates 95 per cent.

I have introduced a few minor details, some of which may be used to advantage at other plants:

(1) Spacing: 4 in. by 3/4 in. iron discs are secured to spacing blocks on the lower face of the outside cleats, on one side only. This is to prevent the blocks from passing opposite cleats when lowering the leaf or when the frame is warped from any cause or when it shifts position, as it sometimes does, from the force of material being pumped into the box. I have found spacing devices attached to the side of box objectionable on account of the accumulation of slime, and also when the spacing is close on account of rigidity. The top spacing is by blocks at the ends, and by irons bent into channel shape between, using two or three to each leaf. They are easily inserted and removed. The frames are held down by a single timber across the centre, resting in two sockets, one of which opens on the side.

(2) Acid treatment; the acid-box is equipped with a vacuum drum for circulating the acid. The leaves are treated..."
once each month, all on the same day, thus maintaining them in uniform condition; although as yet there has been no perceptible increase in the time to form the coking after 30 days' run. Two men can easily take out, wash, and acid-treat 30 leaves per day with an acid-box holding six leaves. The box itself will serve twice that number per day with a vacuum-drum for circulation, and adequate equipment for washing and handling.

(3) Care of leaves: the press when not in use is kept full of solution, the liquid being to prevent rotting of the canvas and precipitation of lime due to evaporation. No spare leaves are in use, soaking in acid or alternately wet and dry. This practice, I believe, tends to rot and slack the canvas. Time alone will tell whether I am right in predicting smooth sailing for a considerable period, if these precautions are observed. Mr. Guthrie claims the simplest-run filter installed up to date is at San Juanito. It may have been at the time he wrote. Our filter was not finished then.

JAMES S. COLBATH.

Smelter-Smoke Consumer.

A process for overcoming the nuisance of smelter-smoke has been tried in West Berkeley, where an experimental plant has been installed by C. Y. De Lay and George C. Carson, mining engineers and metallurgists of San Francisco. The process consists of drawing SO₃ through carbon heated to a yellow heat, where the sulphur dioxide gives up its oxygen to the carbon, as well as any other oxides, such as metallic fume-dusts, and producer-gas (CO) is produced; the equation being:

\[ \text{SO}_3 + 2\text{C} = 2\text{CO} + \text{S} \]

Or, in the case of fume-dust:

\[ \text{Fe}_2\text{O}_3 + 3\text{C} = 2\text{CO} + 2\text{Fe} \]

And

\[ \text{Pb}_2\text{O}_3 + 3\text{C} = \text{CO}_2 + 2\text{Pb} \]

The producer-gas can be utilized for any purpose, such as for firing reverberatories, or for fuel under boilers or in combustion engines. In the experiments thus far conducted crude sulphur has been burned, and the smoke drawn through the carbon, with the result that the sulphur is deposited as soon as the gas escaping has cooled sufficiently to allow the sulphur-vapor to drop out. Some sulphuretted hydrogen forms from the steam or hydrogen in the fuel reacting upon the sulphur-vapor. This sulphuretted hydrogen is removed from the gas by drawing through oxides of iron where it deposits the sulphur, leaving some carbon-hisulphides, which can be almost entirely removed by proper gas-scrubbers.

Another interesting feature developed in the experiments is the application of lampblack for fixed carbon. As it requires fixed carbon for the rections, the cost of coke or charcoal would make the process prohibitive, but crude oil contains about 85% carbon and 15% hydrogen, which, when heated and burned in a chamber with only enough air to ignite the hydrogen, leaves the carbon as lampblack, free from ash. The inventor of the process hopes to develop this latter feature into a process for manufacturing coke from crude oil. A departure has been made from the usual practice in constructing a plant. Instead of erecting a shaft of steel and masonry above the surface, shafts are sunk in the ground, lined with concrete and refractory linings at the points where the temperature would fuse the concrete. A number of experiments have been made at the plant in manufacturing producer-gas from city garbage, which have proved very successful, and the inventor claims that with small changes in the details of the plant, sage-brush or grease-wood can be employed for manufacturing producer-gas. He also has found that stable manure is as easily turned into gas as is bituminous coal.

The heat equation in the recovery of sulphur is exothermic, 2921 calories being absorbed by the sulphur and 4814 calories liberated. Three-fourths of a ton of carbon will recover 1 ton of sulphur, providing the atmosphere drawn through the carbon contains no free oxygen or other oxides than sulphur dioxide to consume the carbon.

In practice any sulphur escaping in the smoke from the furnaces would pass through the carbon, which will catch or reduce all of the fume-dust, so that nearly all the solids after escaping from smelter-chimneys will be arrested and their values added to the output of the plant. The gas produced in reducing the sulphur and fume-dust of the roasters would supply reverberatories and boilers with fuel.

Draeger Life-Saving Apparatus in a Mine Fire.

The following report is made out in addition to a report recently given by the Pittsburgh-Westmoreland Coal Co. on work done with the Draeger life-saving apparatus in the mine fire in the Schoenberger mine of the Pittsburgh-Westmoreland Coal Co. The task before the men was that of putting up four stoppings in a place about three feet high, two of the stoppings from smelter-chimneys were left from the Wage and door. The work on the other two stoppings, which were nearer to the safety-door, was comparatively easy. As the place in front of the stoppings was fairly dry, they were put up in about two hours. During the progress of the work no smoke was met with, and two of the electric Draeger safety-lamps furnished all the light the men needed.

The work of putting up the other two stoppings proved to be more difficult, as the place in front of those stoppings for at least 30 ft. was a deep swamp, and rafts had to be put up in order to enable the men to approach the place. On account of the fact that the men had to travel for this distance on small boards, in a place three feet high, the work of putting up the stoppings had to be done in a stooping position.

After the four stoppings had been roughly put up (one of the stoppings being made of hessian cloth), the supply of oxygen and cartridges ran short, and in order to make these stoppings air-tight, it was decided to open the safety-door and turn in the ventilating current, so as to enable the men to work without wearing the apparatus. Two minutes after the door had been opened an enormous current of explosive gas was directed by the safety-lamps, and the men were hastily withdrawn and the door again closed. We mention this fact in order to show in how strong a percentage of after-damp the men wearing the apparatus had to work. It was then decided to get fresh supplies of oxygen and cartridges from New York. After this supply had arrived in Pittsburgh, the work was resumed, and in about five hours, working with the apparatus, the stoppings were made air-tight and the air turned in again in order to build a solid brick stopping.

It should furthermore be stated that the high efficiency of the Draeger apparatus was proved by the fact that the wearers of the apparatus were able to work for nearly 24 hours continuously, and during this time they were free from any injury. Two men were the first to be warned with the apparatus. The work was postponed and the men were not allowed to work until they had been warned by the apparatus.

Commercial Paragraphs.

C. W. MERRILL, mining engineer and metallurgist, has opened an office at 143 Second street, San Francisco.

The Goldschmidt Thermit Co., of New York, is constructing a new machine-shop, which will be elaborately equipped for extensive repair work by the Thermit process.

BALNEBRIDGE, SEYMOUR & CO., London, announce that George B. Walker is now associated with the firm and will give his attention to reporting and advising on coal and iron properties.

EDWARD B. KIRBY, manager for the Federal Lead Co., Flat River, Mo., will retire on October 15 next, and devote his time thereafter to consulting work, with headquarters at 701 Security Bldg., St. Louis, Missouri.

The Risdon Iron Works, of San Francisco, reports that the Eloorado dredge, at Diamond City, Montana, has started operations on the largest area of alluvial gravel in the
United States. The dredge is one half mile from a famous gravel bar from which more than $4,000,000 was taken in the early seventies. The gravel in this old bench has been turned over three times, and was originally only four feet thick.

Publications Received.

Western Australia, Annual Report of the Department of Mines for 1907.

Many a student and engineer in the field has longed for the freedom of the good old times of Von Cotta, when a man could with some confidence give a name to a rock when he found it. But the petrologists began to discriminate as data increased, and to insist on deference to the revelations of the microscope, until the worker in the field was afraid to even tentatively classify a rock. He scarcely had use for other terms than granite, amphibite, metamorphic, and the like, lest someone threaten him with confusion under microscopic evidence. Mr. Pirsson brings back our liberties. He has undertaken, with evident success, to construct tables and schemes for identification of rocks by their microscopic characters that will be in essential agreement with the classification reached from microscopic and chemical investigation. The work is a clear simple exposition of the leading facts concerning rocks and rock-forming minerals. Simple methods for determining the mineral constituents of rocks are given; general characteristics of rocks, and their relationships; causes of texture, and its significance; inclinations; border-zones; petrographic provinces; and the like, are presented lucidly; after which follow descriptions of the principal rocks, with their relations to each other, their economic significance, and their special uses when they themselves possess economic application. It is a most useful treatise, and will be a great aid in field-study.

Mr. Meade is a man whose experience in setting up laboratories certainly has well prepared him to explain, not merely the leading features, which are matters of common knowledge, but the little tricks and conveniences, and clever time-savers, which mean so much in economy of time and in accuracy of work done under the imperative demand for speed in modern industrial plants. The work covers the field adequately, giving, among other things, an admirable chapter on 'ignition,' in which so many errors are perpetually made; also the chapter on electrolysis is worthy of special note. It is, from cover to cover, excellent in its advice and suggestion, being the product of a finished chemist who knows the needs of the shop and the school. Many an assayer would do well to follow the hints given in this book on sampling and preparation of samples.

The automobile has revolutionized road-making. Not only does the recent road-bed to meet the requirements for endurance under the peculiar wear of the motor-car, but the prevention of dust has also to enter into the road-builder's plans. The most effective subduers of dust are oil and tar, and these are capable of meeting the requirements for durability also. Mr. Judson has written a succinct, practical little book, which should be in the hands of all persons interested in making better roads and in the abatiment of the dust nuisance. The increase in the use of tar in road-making will be a great benefit to the country, through the stimulating it will give to by-product coking, thus aiding in the economy of our natural resources.

This is another product of the activities of the Carnegie Institution in developing a series of treatises covering the economic history of the United States. It reviews the subject of gold and silver adequately though not exhaustively, and outlines the methods of mining and ore treatment to an extent that may prove helpful to one unacquainted with such matters and desiring to obtain enough of the shibboleth of gold and silver mining and metallurgy to better comprehend the annual report of a mining company: One of the most interesting features of the work is the chronology of gold and silver mining in the United States, covering 35 pages, beginning with Ponce de Leon in Florida in 1513. The discoveries of the precious metals and the general course of development of their production, is traced by States. Elaborate tables of production are also given, so that the book will be handy for historical reference.

Catalogues Received.

The Kilbourne & Jacobus Mfg. Co., Columbus, Ohio, has recently issued a new mines-car catalogue, No. 60.

The Cyanide Plant Supply Co., London, has recently published a small booklet descriptive of Brown agitators.

The S. Floor Mfg. Co., Bangor, Pa., has recently issued its 3808 catalogue, descriptive of its line of hoisting engines.

The Union Iron Works, San Francisco, has issued a 14-page pamphlet descriptive copper converters and accessories.

The Union Gas Machinery Co., New York, has issued a small catalogue giving typical designs for producer-gas plants.

The Triplex Roll Co., Denver, has recently issued an attractive pamphlet descriptive of Triplex rolls for ore-grinding.

The Chicago Pneumatic Tool Co., has recently distributed Catalogue No. 26, descriptive of Franklin air-compressors.

The Rix Compressed Air & Drill Co., San Francisco, has recently published its catalogue No. 30 on Torpedo rock-drills and accessories.

Dean Broe, Indianapolis, have lately published catalogue No. 71, which gives complete description of and information concerning Dean steam-pumps.

The Western Lubricating Valve Co., Denver, has lately distributed an extensively illustrated booklet descriptive of its line of lubricating valves for rock-drills.

The Eureka Drill Steel Co., Denver, has lately sent out a small booklet setting forth the advantages of Eureka drill steel for the manufacture of rock-drill bits.

The American Spiral Pipe Works, Chicago, has recently issued an elaborately illustrated booklet (No. 25) descriptive of spiral riveted pipe and fittings thereof.

The Goodwin Mfg. Co., Chicago, has recently issued Bulletins No. 301 and 501, the first of a series which will eventually comprise a complete catalogue of electric mining machinery.

The American Steam Gauge & Valve Mfg. Co., Boston, has issued a pamphlet on steam-engine indicators, which is not only a catalogue of the apparatus supplied, but is a complete restatement and a digest of the earlier publications.

The Burstol Co., Waterbury, Conn., has recently issued Bulletins No. 91 and 93, which, together with No. 22, issued in June, make a complete list of recording thermometers for all temperatures up to 800°F. All three pamphlets are handsomely printed in colors, and will be valuable additions to any library of trade publications.
ON October 1 the 95th meeting of the American Institute of Mining Engineers is to be held at Chattanooga, Tennessee. Excursions will be made to Ducktown, and these will include the two important copper mines and smelters.

THE NEW MILL of the Sumner Deep company at Johannesburg will have 300 stamps, each of which will weigh 1670 pounds. In the design of the mill, three main principles have been kept in mind, namely: Simplicity of arrangement, large units (such as 50-ft. sand-vats and 70-ft. slime-vats), and facility for extension of the plant.

METAL operators will be interested in reading the letter from our correspondent at Melbourne, Australia. We hear the echo of a growl that went round the world when Mr. H. H. Rogers and his piratical crew undertook to play with the copper market for the benefit of Wall Street. The disposal of the Broken Hill lead and the Mt. Lyell copper is a matter of some moment to the American market in these metals, therefore the gossip of Melbourne will prove timely. Our correspondent refers also to the successful treatment of zinc concentrate at Broken Hill, and his statement is confirmed by letters received by us from London.

SIGNS of impending trouble gather in the Coeur d'Alene. The convergence of a group of mining experts, including Messrs. Ross E. Browne, Albert Burch, J. R. Finlay, and W. J. Elmdorf, at Wardner, Idaho, suggests the resumption of litigation over apex rights between the Bunker Hill & Sullivan and the Federal Mining & Smelting companies. Mr. Pope Yeatman is there in the interests of Mr. Daniel Guggenheim and of peace, for the New York financier is interested in both enterprises and is likely to view with alarm the clash of the courts. Should hostilities supervene we shall see a further obfuscation of mining geology as viewed through the smoked glasses of the law and another exemplification of the insecurity of title due to the interpretation of regulations based on non-selene.

IT MUST be confessed that W. R. Hearst has done a service to the country by his exposure of the venality of sundry legislators. Moreover, it is noteworthy that the fact surprised no one; just as we in San Francisco believed the former supervisors to be corrupt and yet barely hoped to see them exposed, so the average business-man understood Foraker and Sibley to be hirelings of the Standard Oil Company without the hope of seeing any end to their pestilent energy in the cause of national corruption. From Wall Street we learn that the exposure of the Arch-
bold-Foraker correspondence has "shaken confidence among capitalists," and it is whispered that disorder in the stock market is to be fostered in order to warn the public of the danger of reviving political activity against the big corporations. Thus every movement of reform is crippled, for the predatory financiers have scattered their stocks among "the widows and orphans" so that those proverbially deserving citizens have become partners with Harriman, Rogers, Archbold, and Foraker. Those who desire freedom in the throwing of stones should not live in glass houses, and the people who hope to purify national life had better begin by careful abstention from buying the shares of corporations dominated by enemies of the Republic.

Lives of Mines.

Men think all men mortal but themselves. Miners recognize that all mines must come to an end some day, except their own. Occasionally it is well to remember even our own mortality. At times, it is proper to emphasize the fact that the best of mines is a treasure-valet of a necessarily exhaustible character. As a rule it is not possible to predict the date at which a mine will be so stripped of its ore as to be a worthless hole in the ground. Where a mining property possesses ample room to follow an ore deposit on its dip or on its strike, or where unquestioned apex rights afford the opportunity to explore indefinitely in depth, the end is postponed and is reached only when either the capital or the pluck of the shareholders has been bottomed. Time and again 'worked out' mines have been rejuvenated by the skill and good fortune of enterprising operators. Thus the Gwin mine, in Calaveras county, California, was re-opened by Mr. F. F. Thomas and his friends when it lay abandoned; the Camp Bird, in Colorado, was based on a prospect started twenty years before it became a mine, and supposed to be worthless until Mr. Thomas F. Walsh took a lucky sample from the old workings; the great Nevada Consolidated copper mine was built upon the ruins of earlier unsuccessful enterprises. A rise in the price of a metal, the invention of a metallurgical process, a revival of interest in a mining district, or some other improvement in the conditions affecting profitable operation will stimulate a hope and cause an operator to expend capital in reviving a mine supposed to be dead. For these reasons men hate to acknowledge finality in the possibilities of any given mine. This sways sentiment in the opposite direction, until there is a general obnubleness to the recognition of the brutal fact that there must be a sure end to all reserves of ore. By 'ore' is meant rock containing mineral of such a kind and in such proportion as to be profitably mined at a given date. It is no consolation to a business man to hope that the ore unprofitable today will, by improved economic conditions, become a source of profit twenty years hence. Mines are rarely bought or mining shares purchased in the expectation of waiting for indefinite changes such as will enhance the value of the product of the mine. The miner lives in the present, the past belongs to the scholar, and the future to the philosopher; the man with the pick deals in actualities.

Until the Transvaal mines were developed it was not the custom to speak of the 'life' of a mine; in fact, it was deemed indecent, as conveying a mortuary suggestion. But when it was proved that the 'banket' lodes were of unusual uniformity as regards width and value, it became a cheerful task to assure shareholders of the certainty of a life of profitable productiveness for a term long enough to change a 'speculation' into an 'investment'. Mining companies at Johannesburg own a varying number of claims; in a given area they possess a vein, or more than one vein, which they can work within their boundaries, vertically extended, but no farther. They have rights of aereage but not of apex. Given a defined tract and veins of supposedly uniform ore and of regular dip, it was easy to compute the number of tons of gold-bearing conglomerate that could be extracted; and given a mill of specified capacity, it was not difficult to estimate the number of years during which it could be kept going. Having assumed the physical factors, the investor turned to the financial side of the problem, and taking for granted a dividend at a given rate, he made provision for amortization of his capital by setting aside part of the dividend, after allowing for a net return of 6 or 7 per cent. Naturally it was easier to make calculations on paper, or estimates in a busy brain, than to find ore deposits conforming to such assumptions of lovely regularity and sweet continuity. The promoter made the most of the charming idea of a tabular lode of uniform richness that behaved with the perfect conformity of a theory in a stockbroker's text-book on geology. Thus, for example, a property consisting of 200 claims and a six-foot reef inclined at fifty degrees would yield 49,800 tons per claim, or 9,960,000 tons altogether. If the mill crushed 400,000 tons per annum, the productive life of the mine would be twenty-five years. If the revenue were thirty-five shillings per ton, the cost twenty, then the profit would be fifteen shillings, equivalent to £300,000 per annum, or a dividend of at least fifty per cent on a capital of £500,000. By referring to annuity tables the present value of ten shillings (the annual dividend) for twenty-five years is found to be £5 3s. 4d. Yes, it was lovely while it lasted; and it induced millions upon millions of money to be extracted from the British, French, and German public. But it was an iridescent dream. The arithmetic was flawless but the geology was visionary. No gold vein was ever created up to the standard of the London promoter's imagination. In the course of actual mining it was discovered that the dip of the lodes was not regular, that dislocations were caused by dikes so as to increase the cost of extraction and to diminish the tonnage available; that the ore varied in richness, being sometimes too poor to yield a profit; that the width of ore was not constant; in fine, the assumed uniformity was nonexistent, the vein-structure proved to be like vein-structure anywhere else in the world, namely, subject to breaks, irregularities, and variations such as constitute, and always have constituted, the sport of
mining. True, the Rand deposits have a persistence and even a regularity above the average, and they have furnished the basis for a magnificent industrial development, but it cannot be sufficiently insisted that the mines of the Transvaal are not hasse concours; that they are not superior to the vicissitudes of mining; that they are not a fit subject for childlike calculations.

The experience of the Wenner, City & Suburban, and Roodepoort United companies proved that the lives of mines, like those of humans, are subject to untimely ills, while the record of the Bonanza, Pioneer, and one or two other mines proved that properties apparently exhausted may yield ore beyond the estimates of engineers. Mining is essentially speculative, and no wise man will allow himself to brood the notion that even the best mine is either inexhaustible or accurately appraisable, any more than the ‘expectation of life’ to an annuitant. Estimates of the longevity of a mine must be taken with reserve; at the best they are close approximations, dependent upon factors some of which are quite beyond control. Thus, for example, statistics published in the reports of the Transvaal Chamber of Mines giving tonnages of ore available in various mines, together with the assay-value per ton, are impressive and interesting, but we venture to say that if they are compared with the results as revealed after ten years’ production, there will be enough divergence to afford a text for remarks such as we have already made. Eleven mines at Johannesburg are credited with reserves in excess of 1,000,000 tons of ore, ranging in gold content from 6.5 to 11.97 dwt. per ton. The finest showing is made by the Robinson, which has 2,779,236 tons averaging 11.97 dwt. per ton, that is, a gross reserve of $33,250,000. This has been the basis of calculations that regard the ore underground as if it were specie in a bank, while, as a matter of fact, during the six years required to exhaust this treasury of nature there is a possibility of many untoward happenings, such as interruption of work by reason of labor troubles, caving of workings, fire underground, destruction of the mill, and other disasters such as are known to have happened to mines in South Africa and elsewhere. Not that we wish to belittle the splendid mine that has been the leading gold producer of the world for several years, or to under-estimate the excellence of the technical management that has placed it in such an exceptional position. We desire to emphasize the fact that gold mining, whether on the Rand or in Nevada, whether in New Zealand or in Alaska, is essentially a glorious speculation, yielding returns the bigness of which compensates for the uncertainties, the risk of which is balanced by the profits. Sure things are dangerous, for a mine whose life can be accurately appraised is most unlikely to last longer than the estimate, its value is put at a maximum, and any error is likely to be on the wrong side. The big money in mining is made by developing a young possibility into a profitable property; when a mine is finally developed, it is well to let the other fellow have the ‘investment’ while you look around for another ‘speculation’.

James D. Hague.

OWING to special circumstances, no mention has been made in these columns concerning the recent death of James D. Hague. Nowhere is he more honored than in California; by none are his services to science and industry better appreciated than by the older readers of this journal. When he was in San Francisco last spring we noted that he had aged rapidly during the past year, and therefore the sad news that his life was ended was not as great a shock as it was to those who thought of him always as a charming personality, as temperate as he was healthy, as genial as he was philosophic.

Hague was one of a group of men to whom mining in America owes a great debt; he, Clarence King, Emmons, Beeker, and Raymond were the men who first gave a right direction to the application of geology in mining operations; and they did more, for they proved how great a factor character could be in shaping a successful industry. Most of them obtained their early training at Freiberg, for the Columbia School of Mines was not founded until after they had begun practice. Hague left Freiberg in 1858. In 1863 he made the first report on the Calumet & Hecla deposit of copper ore and in later years he was properly proud of having taken a useful part in so notable a mineral development. In 1867 he joined King on the Survey of the Fortieth Parallel and made important geological investigations in the West. In 1871 he became directly connected with gold mining in California, especially at Grass Valley, where he directed the opening of the North Star mines, one of the cleanest, most intelligent, and most successful of American mining enterprises. This brought him periodically to California, even after he had retired from active consulting work. Hague was necessarily an authority on all national mining problems; he served on important commissions both at home and abroad. He wrote occasionally to both the technical and secular press, and he was always to the point, careful, sane, scholarly. One of the literary productions in which he took pride was the ‘Memoirs of Clarence King,’ to which many notable men contributed, and which Hague edited with an accuracy and fidelity rare in these days of reckless hurry. This was published in 1904. After the disaster of April, 1906, Hague came to San Francisco as representative for the New York Chamber of Commerce, to advise concerning the use to be made of the $500,000 donated by the Chamber for the benefit of the sufferers by the earthquake-fire. He was admirably fitted for this benevolent duty, and performed it with the conscientious diligence characteristic of him in all his doings. In these days of private and public graft, at a time when the finance of mining resembles a hippodrome on the edge of a penitentiary, in a period marked by intensive pursuit of the shiek and the successful evasion of moral obligation, it is fitting to record the heritage of a fine example, the stimulus of a life that combined the skill of the engineer with the science of the geologist, the enterprise of a financier with the honor of a gentleman.
Personal.

William M. Brewer is here.

M. L. Requa is at Salt Lake.

W. F. A. Thomae is in Colombia.

J. R. Finlay is at Warden, Idaho.

Arthur Winslow is expected here shortly.

Skeley W. Mudd was in San Francisco this week.

T. A. Campion, of Chicago, is on his way to Nome.

Alfred H. Brooks was at Nome early in September.

Philip C. Storrs has gone from Scattle to Valdez, Alaska.

O. B. Perry is expected in San Francisco about October 1.

J. W. Mearns sails from New York for Ecuador on October 15.

W. L. Leland was in the railway accident near Nome, but was unhurt.

George A. Dale, of Leadville, Colo., is spending a few days in San Francisco.

Scott Turner is remaining at Nome for the remainder of the present season.

Javet Lindeberg has returned from the Amadik concessions in eastern Siberia to Nome.

Howard W. DeBois passed through San Francisco on his return from Dawson to Philadelphia.

W. J. Adams is in Tulalumne county, California, and will return to San Francisco on October 1.

F. W. Bradley is making one of his periodic visits of inspection at the Bunker Hill & Sullivan mine, in the Cœur d'Alène.

George W. Boardow has returned from Western Australia, where he was manager of the Great Boulder Perseverance mine, and has opened an office in the Millie Bcg., San Francisco.

Daniel Guggenheim, James Phillips, Anton Eilers, Karl Eschebach, W. Stewart, Edgar Newhouse, W. R. Rust, and Eugene B. Braden are at Salt Lake last week; and the three first mentioned went thence to El, Nevada.

William Frechville, William Campbell, Hugh T. Markert, and J. C. Murray (editor of the Canadian Mining Journal) are among those in attendance at the meeting of the Canadian Mining Institute at Victoria, British Columbia.

J. M. Boutwell, who has been engaged in mining work for the government in western districts during the last ten years, has resigned his position as geologist on the U. S. Geological Survey. He will engage in mining geology for private interests, and is now on his way from Washington to Bisbee, Arizona.

Obituary.

Cabell Whitehead died at Nome, Alaska, on September 7, in consequence of injuries received two days previously in an accident on the Seward Peninsula Railroad. The train was derailed and Dr. Whitehead was thrown into a pool of cold muddy water under some lumber, which was part of the trainload. He was pinned under the lumber for a couple of minutes, so that his lungs were filled with the silt and cold water. On being extricated, he recovered sufficiently to be able to speak, but acute congestion of both lungs supervened, and a fatal result was inevitable. Dr. Whitehead was one of the most influential and useful citizens of Nome. He owed his title to a Ph.D. degree. As consulting metallurgist to the U. S. Mint he was well known. He came to Nome in 1900 as representative of the Bureau of the Mint, and shortly afterward founded the Alaska Banking & Safe Deposit Co., of which he was president at the time of his death. He made the first trustworthy report on the future of the mining industry on the Seward Peninsula; this was at the close of the summer season of 1900 and was made for the U. S. Government. He resided from the Government service in 1901 and soon afterward organized the Topok Ditch Co., in which enterprise he was supported by Henry Bratsober. He was born in 1884, at Lynchburg, Virginia, and was descended from an old colonial family. His education was obtained, first at Lehigh University, where he was graduated in mining in 1885, and then at Columbia University, from which he received the degree of Ph.D. His work lay mainly in the assay department of mining, first at Boise City, Idaho, and then at Washington, D. C. In 1895 he went to Europe to investigate methods preparatory to the building of a new mint at Philadelphia. He made a special study of electro-metallurgy and contributed several valuable papers on this subject. In 1898 he established the assay office at Seattle. He is survived by his wife and he is also mourned by many friends. At Nome he was a dominating figure and played an important part in the development of the Seward Peninsula. He was manager and president of the Seward Peninsula Railroad, on which he was killed, having resigned control a week before the fatal accident. A man of fine presence, conspicuous ability, and unusual culture. It is not too much to say that his untimely end is a tragic event in the history of Alaska.

General Mining News.

ARIZONA.

COCHISE COUNTY.

The Keystone Mining Co. is to be incorporated to work a group of nine claims, at Johnson camp, belonging to Alex Bannon and W. W. Miller. The capitalization is $900,000 in shares of $1 each, 100,000 of which will be placed on the market for public sale. The new Company is composed of well known Kansas men. The group, of which the St. George is the principal claim, is surrounded by such properties as the Walker & Williams, the Arizona Consolidated, and the John Gleason.

MOHAVE COUNTY.

George Fisher, of Chloride, has a contract to sink the shaft of the Horseshoe mine, at Cerbat, to the 150ft. level. The shaft is now almost to the desired depth, and contracts have also been let to Mr. Fisher to crosscut several veins in the Horseshoe group and also to drive 100 ft. in each direction on the vein. Work is progressing rapidly and it is the intention of J. W. Thorn, general manager of the property, to keep development on the move the next twelve months.

YAVAPAI COUNTY.

The Gold Ridge M. & M. Co. has been incorporated to work the Mark Hanna group of claims, near Congress, formerly owned by Byron Smith of Wickenburg. Mr. Smith has been appointed superintendent and has gone to the mine to start work. The property is in a practically proven belt, the Alaska and Zeiger ground both having been developed to the producing stage. — The Octave mine is undergoing considerable change in the way of surface improvements pending the time when electric power can be transmitted to the camp. The miners have all been laid off and a force of men is now employed in tearing out the boilers and doing other work preparatory to the installation of electricity. Two new head-frames are being placed on the main working shafts in order to increase the hoisting capacity. The old cages will be abandoned and skips will be used instead.

CALIFORNIA.

AMADOR COUNTY.

The Keystone, at Amador City, has been bonded by a company of Philadelphia men, and it is understood they will at once proceed with development work. There is ample capital behind the promoters. The mine has not been developed to any great depth. The Keystone is the oldest mine in the county and has been operated continuously for over 50 years, but only in a small way during the last few years. — The Gwin mine has been abandoned and all underground machinery removed. The Company is engulfed with indebtedness, although the stockholders still have faith in the mine, and it is probable that some reorganization scheme will be undertaken. — The Copper Hill mine, near Latrobe, is getting ready to ship its first consignment of rock to the smelter. Some five years ago the find was made and operations were begun. Two steam hoists are now busy bringing ore to the surface and the shaft is down 900 ft. The ore taken out of late has been getting better and the force of men has been increased until now there are 61 men on the pay-roll. Five eight-mule teams are ready to haul the rock to Latrobe, a distance of about five miles.

ELDORADO COUNTY.

The new 10-stamp mill recently completed at the Sherman mine is now crushing ore night and day, the capacity being about 40 tons per 24 hr. The mine is opened by a double-compartment 700-ft. shaft. The vein is 12 ft. wide in some places, and carries free gold to the amount of $150 to $200. A force of 25 men and six air-drills are at work. George Clark, of Placerville, is the superintendent. It is probable that the force will be doubled when the ore surplus, which accumulated while the mill was being built, is exhausted.

NEVADA COUNTY.

(Special Correspondence). — A small pump has been installed at the Hill mine and the work of unwatering the shaft is about to start. — A movement is under way to resume operations at the Woodberry mine, which adjoins the Sultana group. Machinery will be installed. — Arrangements are being made to drive Tunnel No. 7 on the South Yuba copper mine to considerable depth to strike the large orebodies exposed in the upper adit. — Practically all the men recently laid off at the Sultana mines have returned to work on tribute. About 50 are working.

T. H. Kohler has struck a large vein of milling ore on his Eagle Bird Ex. claim, at Maybert. On two other claims good bodies of ore running from $22 to $30 per ton have been proved. — The foundations for the hoist and compressor have been practically completed at the Noramango, and within a few days the work of installing the machinery will be under way. — Henry Broul and J. R. Selfridge, of San Francisco, are inspecting the Arctic mine on Canyon creek. — A company of Pittsburgh capitalists, headed by J. H. McKaig, have decided to commence operations at the Snow Point mine. George Hegarty is superintendent. — The Searchlight G. M. Co. is actively developing the Star claim with the expectation of reaching the extension of the Crewn Point vein. — A. M. Gilbert of Santa Barbara has secured a bond on the Oustomah and is arranging to soon commence activities with a large force of men. — The Grass Valley and Nevada City districts are full of idle men, despite the fact that more men are working at the present time than for many years. In the Granville district a dearth of labor is reported.

Grass Valley, September 21.

PLumas County.

The Arcadia group of mines, on the east side of North canyon, has been bonded to W. B. Deveraux and son, of New York, for a period of one year. More men will soon be put at work. — Dredging at the Cash Rock is delayed by big boulders which have to be blasted. As the divers are not drill men, they make slow progress at blasting.

SAN BERNARDO COUNTY.

A strike of rich ore was made last week in the adit on the Oro Belle No. 1, at Hart. A streak of $300 ore, from one to three feet wide, has been uncovered for a distance of over 50 ft. In addition to this rich show there is four to six feet of milling ore, averaging $15 to $20 per ton, which will be sacked and sent to the Little Giant mill, at Seareight.

SIERRA COUNTY.

A company of San Francisco men, represented by A. D. Gassaway, has taken a bond on some 2½ miles on the east side of the Scales-Port Wine ridge, including the Hard-scrabble, Poor Boy, Bon Ton, and Monitor claims. The new company will start prospecting at once and prepare for active work next spring. — The mill at the Gray Eagle mine, at Gold Point, will be started next week. Jason Frye has set the new concentrators and everything is now in first-class order. An assaying outfit was recently purchased.

—Joel Bean has recently sold his gravel mine on the Scales-Port Wine ridge to a San Francisco company, which now has men at work developing the ground.

COLORADO.

GILPIN COUNTY.

The Golden Sun adit is in 1400 ft. and some good copper-iron ore is exposed in the breast. A drift has been started on the last vein cut. Heavy rails are being laid in the adit and mule-hauling is to be used in the future. — G. M. Ashmore, manager of the Smuggler property in Moon gulch now operated by the A. K. R. Gold M. & M. Co., reports that the clean-up during last week, which represented about two weeks' run in the mill, was 96 oz. of gold, which sold to the Denver mint for $19 per ounce, bringing in $1824 for the lot. Two cars of concentrate were shipped to the Denver smelters, the first car being loaded for the rate of $25 per ton, while the last car sampled $76 per ton, being of a much higher grade. Decatur, Illinois, people are interested in the property together with Mr. Ashmore, and so
well pleased are they with the property that they are going to add five stamps to their mill capacity, overhaul the mill generally, and install a 60-hp. compound engine and an 80-hp. boiler, also an air-compressor plant.—R. I. Hughes, of Russell Gulch, and B. F. Threewit, of Denver, have become interested in a lease and bond on the Hughes mine on Bellevue Min., and have been doing some preliminary work during the past month. They have arranged for the installation of a first-class plant of machinery, the erection of a new shaft-building, and will start actual development as soon as the machinery is in place.—Chicago people have become interested in the Cœur d’Alene mine on Academy hill, and J. F. McBride has been out from Chicago during the past week to make arrangements for starting up the property. Mr. Bolander, of Blue Hawk, has been placed in charge of the operations, and the first work to be done is the installation of a 45-hp. hoisting engine. The property is leased from Mrs. Catherine Cameron, of Denver, for a period of 97 years, and the operators are planning extensive developments in the lower levels, as well as the deepening of the shaft, which is now down about 600 feet.

LAKE COUNTY.

Arrangements are under way for the electrification of the new Berdella adit in the St. Kevin district. A force of men is now erecting the new plant at its portal. Connections will be made with the lines of the Central Power Co. which pass near the site. While this work is going on, activity in the breast of the adit is temporarily suspended, but as soon as the machinery is in place and the power is connected with it, the bore will be driven ahead with renewed energy.—Work has been resumed on the Aztec prospecting mill near Twin Pikes. A drift will be driven into the orebody that was opened about a year ago. The ore carries two or three ounces gold, some silver, and a good percentage of lead. Hauling to the railroad at Granite will be started in a short time, as shipping can be done from the streak now in sight. It is proposed to keep the mine open all winter.—Over in Willis gulch, a promising discovery was made in the Manhattan property a few days ago. The adit passed through an ore streak 14 ft. wide. The vein is now being followed out in several directions. Tests of the ore have been made which show it to be of good milling grade. As the property is far from a railroad, the erection of a mill is being considered.—Spruhan & Pasco, who are working the American property in Iowa gulch, have recently opened a vein of iron carbonate from which about 35 tons have been shipped. They have also had some work on the old Ruby property in the Western Pass district, which is to be operated this winter by A. S. Sharp, manager of the Aurora mine in Iowa gulch. Mr. Sharp will continue to look after the Aurora while handling the interests of the Ruby.—The lessees of the Progressive, or Kady shaft, have temporarily quit work owing to the fact that their overboy dipped, necessitating sturdy pampling. A re-organization of the leaseholders is in progress, and when completed work will be resumed.

OURAY COUNTY.

A temporary decrease in force on the Atlas mill has been made necessary by the condition of the development work at the mine. It has been found that the treatment of the Klondike lead-silver ore through the Atlas mill is not paying, and that a large amount of silver is being lost. Tests are being made to determine the process best suited for the ore.—The Ouray Con. Mines Co. started work last week on its Biowoot adit in the Gold Belt. Only one shift is now at work, but another will be put on later.—The First National, on the western slope of Mt. Hayden, will soon start a force of miners extending its adit, to strike the big ore-shoot exposed in the upper workings. R. W. Clinton is the superintendent.—The Poland, now under lease to W. S. McCarthy and E. C. Bacon, is taking out a mill run, preparatory to making a carted shipment. The ore being broken is high-grade silver with about 7% copper.

SAN JUAN COUNTY.

It is reported that the Hamlet mill will soon be operated again. The development of the mine has been going steadily onward and a large ore reserve is now in sight.—Work has been temporarily suspended at Koehler adit because the San Antonio Mining Co. required the contractors to keep sufficient funds on deposit to meet their current expenses, thus safeguarding the interests of all concerned, most especially of the miners.—Sam Dresbach, Arthur Landry, and C. A. Marshall have taken a lease on the Anti-Periodic, belonging to Matt Salmofero, and will begin operations at once. They expect to make some good shipments before snow flies.

SUMMIT COUNTY.

The Wellington mine, at Breckenridge, is being equipped for handling a heavy tonnage of ore. The Wellington mill is expected to be in operation at an early date. It is believed that the Wellington dump will bring $7 per ton, and that the shipping ores will bring something like $40 per ton, as indicated by smaller returns. The ore in sight in the property is said to amount to 250,000 tons.—The Penn Ores Co. has resumed work on the Hoxen property, in French gulch, in which the long adit cut a strong zinc-lead vein.—The International Co., which opened up an extensive body of lead-zinc sulphides some months ago at Robinson, and, after testing it thoroughly, closed down to take stock of the situation, is expected to begin the construction of their new mill during this month. It has not yet been definitely decided whether to build in Summit county or at Leadville, but probably the latter will be selected as the site. The mill will include crushers, sizers, and Wilfley tables.

TELLER COUNTY.

 Hoyt and associates, who lately secured a lease on the Wreckoff, at Cripple Creek, have loaded out three ears of ore since assuming the lease, which have returned the lessees from $15 to $20 per ton. The operators have not attempted to break any mineral in the property and have confined their attention to shipping the ore left in the stopes by previous operators.—A two years’ lease, with royalties graded from 15 to 30%, has been granted by the Acacia Gold Mining Co. to Calfour & Maginn, of this city, on a block of the Burns claim on Bull hill. A lease on similar conditions has also been granted by the Acacia management to A. J. Busch, on a block of ground covering 200 ft. in area situated on the east side of the Wreckoff shaft and extending to the 400-ft. level. In all there are nine sets of lessees operating on the Morning Star and Burns claims of the Acacia company, and with the exception of the last two granted, all are producing. Operations are now deemed by them to be of permanent character on the western slope of Reason hill by the Julia V. Mining Co., owning the Henry Adney mine. A new compressor and machine drills are to be used.—A complete plant of mining machinery has been installed on the Colorado Boss by Cleaver & Sharp, of Cripple Creek. The property is under lease to Judge Wilson, of the Black Hills, South Dakota, and will start actual operations soon. The outfit consists of an electrically driven compressor and an 8 by 10-in. geared hoist, with the other necessary machinery to operate the property. The Colorado Boss is on the south slope of Gold hill.—The 100-ton ore-house at the portal of the Comanche Plume adit was completed last week.—Morris and associates, who recently secured a lease on advantageous terms from the management of the Longstreet Co., on the Ruby Mountain, are trying their luck on the northern slope of Gold hill, are mining ore at a depth of 55 ft. which assays from $15 to $25 per ton. The new shaft sunk from surface by the lessees is at present equipped with windlass only, but should the pay streak hold out, a steam or electric hoist will be installed. These leases are preparing their trial shipment.

IDAHO.

IDAHO COUNTY.

Two feet of free-milling ore which assays more than $500 in 5 lb. was struck in the course of the main adit in the South Fork (Espey) mine in the Elk City dist. a few days ago. The ore-shoot will be developed by running a drift west and sinking a shaft. This is the rich-
sett strike yet made in the mine. A five-stamp mill was put in operation a week ago. With a crude equipment Mr. Espey, the former owner, took out $2140 in 14 days. Since then the mine has been developed by a 700-ft. adit on the vein and several cross-cuts to parallel veins.----Ore said to be of the highest grade yet found on the property has been opened on the 400-ft. level in the famous Buster mine at Elk City. The discovery was the cause for much rejoicing in the camp, as it proves that the rich ore found in the upper workings holds out at depth and indicates that the same results will be achieved in the development of other promising properties in the district which have big surface cropplings.

NATZ PERE COUNTY.

There is more than ordinary activity in the Pierce district in Central Idaho. Modern methods are taking the place of crude operations of the last decade and large areas of placer ground that was thought to be entirely too flat to work under the old system by sluicing are now being worked successfully by dredge and hydraulic elevators. I. D. Cleek now has 25 men constructing the largest ditch and opening up the largest placer property ever operated in the district. This property is situated 12 miles northeast of Pierce.-The Ozark M. & M. Co., which owns the Ozark and the Wild Rose groups, has installed a new air-compressor and is making progress with its lower adit, which is now in bel mined sale has been set for December 16. Officers and directors were chosen for the ensuing year, an encouraging report of the Company's finances and the development of the property was submitted. Work has started on the 4000-ft. adit of the Flynn Group Mining Co.'s property at Black Oak. A small force of men has been engaged and it is not expected that a great deal of development will be done this winter, but it is the intention of the Company to install a compressor and full line of equipment and to have everything in readiness to push development next spring. In the upper workings of the mine a good showing of ore has been made, but no shipments will be started until the long adit from the railroad has been completed.----The Capitol Mining Co. has started work on a lower adit of a depth of 697 ft. and deeper than the upper workings. This Company will also install a full line of machinery in the near future. Already almost $50,000 has been spent in the upper development and the management believes that with the completion of this adit the property will be in a position to commence shipments and to start up its own mill.----On the completion of another 1000-ft. of adit work is believed that the Neverwasser Milling Co., a close corporation, will commence regular shipments of ore. Some time ago ore was found at the foot of a shallow shaft and the owners decided to sink deeper. Since then the shaft has been sunk about 52 ft., and the quality of ore continues to improve at such a rate that it is believed that with a little more depth the property will be on a shipping basis. For more than 12 years this mine has been operated, but until recently nothing better than milling ore has been discovered. The ore assays about $37 in lead, silver, and gold per ton, but no attempt has yet been made to ascertain the extent of the orebody.

C. C. Titus, manager of the Panhandle smelter, was in the Coeur d'Alene district the middle of last week and made the announcement that the first furnace of the smelter would be blown in between October 1 and 10, and the second furnace about ten days later. Mr. Titus states that he is now in the process of making several workings on another vein and that it has already 1890 tons on hand. His visit to the Coeur d'Alene was for the purpose of closing more contracts. A force of about 75 men is at work on the smelter and already more than $75,000 has been expended on the new roasters. The new company has agreed to accept shipments of five and ten-ton lots, provided that these are made in the name of one man, so that the shippers may get the benefit of carload freight.

Wallace, September 19.

MISSOURI.

JASPER COUNTY.

(Special Correspondence.)--With a higher and steadier zinc ore market a great wave of mining activity is sweeping across the district, the past few weeks having seen the properties closed down for months are preparing to operate again. A number of zinc smelters are re-opening for the first time since the panic, and as they use the Joplin ores this move will furnish an additional reason for increased activity among the mines of this district. The new Hegeler Bros. smelter at Danville, Ill., has opened and will buy most of the ore from the Joplin field. Recently, the Zinc Co., at Okla., at Iola and Gas City, Kans., have all started the furnaces after a continued shut-down. All have buyers in this territory.----The White Dog Mining Co., operating north of Webb City, started its plant after a prolonged shut-down. A thorough overhauling of the mill was made and modern improvements installed. The old level at 147 ft. will be re-opened, as well as a deeper level at 161 ft. which in old days has never been worked.----The main plant of the old Ideal, southeast of Joplin, started again after a shut-down of almost a year. Several sub-leases have been working in the meantime.----The old Bumble Bee mine is being drained with a view to re-opening at once. This is one of the old and rich producers in the field. The ore occurs from 110 to 198 ft., and is very rich, often consisting of large chunks of pure zinc which is in all districts has been thoroughly drilled and operated for some years. Marquis & Co. are re-opening the Innovator, at Prosperity. Under the former management the mine proved unsuccessful and passed into the hands of a receiver. The present Company is opening a new drift and already more than paying expenses. The mill is a 150-ton plant.----The Pittsburg-Mineville Co., has opened an old silicate deposit in Leadville Hollow, at the 50-ft. level. A 10-ft. face of the ore has been opened, running 3 to 10% silicate and 4% zinc-bloody.----A few more weeks will note the completion of a number of mills in this county, which will be ready to operate upon well developed ore deposits. Among these may be noted the Coahuita, at Porto Rico, which is almost finished. It is one of the largest and best equipped in the district.----A falling mill has just been completed on the Blackberry lease, at Smelter Hill. A large pile of tailing, the accumulation of years, is awaiting treatment.

The Thirty Year Mining Co. will soon erect a mill to treat the ore which has been opened up in East Hollow. Thirty acres are under lease and nine shafts are in ore. This is an old tract operated years ago from 60 to 90 ft. lower levels are being developed and rich stopes 18 to 24 ft. thick are being worked.----Matte Bros., who have finished the development of 24 acres west of Joplin, will move the old San Gabriel mill from their lease, at Porto Rico, and re-model it to meet the different ore conditions found in the new lease. The tract was thoroughly drilled and four shafts sunk in the ore. A west was made and a new zinc conditioner at Alfa will re-model and use the old plant for a tailing mill and will erect a new 40-ton mill to treat the ore.
About 7 or 8 tons of ore is treated per shift. The ground has been well developed and three shafts are in ore at different levels.—Among the strikes of the past few weeks the Leonard strike of galena, at Leadville Hollow, is important. A shaft was sunk on this lease to catch the rich run opened up on the adjoining Try More lease. At a depth of 3 ft. a rich galena run was entered. The drifts of the Try More have been connected with the Leonard, and excellent ventilation is secured for both mines.—A good deposit of galena has been struck in the Kansas City bottoms by Solbert & Risler. The run occurs at 35 ft. with a working face of 8 ft. high. The zinc-blende run, which occurs below the 60-ft. level, will be opened later.—A good galena mine has been developed in the Dueseberg country. Has Boomer, of Silver City, S. D., 800,000 lb. of zinc and over 2,600,000 lb. have been taken and only a third of an acre has been mined. This record has stimulated interest in prospecting and a number of drills are busy. As a result a strike has been made by Henry Wayman on adjoining land where the ore is being taken from shafts sunk only two to ten feet. The galena is good grade and several tons have already been shipped to the smelters. Over 200,000 ft. of ore has been developed by which 22 of which penetrated the ore. Dan Bristow and associates are developing one tract and are treating the ore on hand jigs. Two to three tons per day are turned in. Dick Blesser is drilling a second lease of ten acres, on which some rich strikes have been made. A third sub-lease is being developed by Snyder & Watkins, who will erect a mill. This lease embraces the old Cardinal tract. Two shafts are in ore.—In the Caribou camp the Caribou Investment Co. is pumping the old Chotwell tract preparatory to re-opening it. A 15-ft. face has been opened in a drift running as high as 25%. The mill has been on the ground several years and is equipped with all necessary machinery. Operations will be begun as soon as the ground is drained. The Venus mine, northwest of Caribou, and the Davey farm, has been purchased by the D. J. Telephone Co. Dividend camp is of the hardy year. Since last February the mine has produced $1,238,790 of zinc-blende bringing an average of $34.87 per ton. Out of this $57,250 in dividends have been paid.

Joplin, September 19.

NEWTOWN COUNTY.

(Special Correspondence).—A contract has been let for the erection of a new 250-ton mill on the Grady M. & S. Co.'s land, at Granby, to take the place of the old plant which has been in operation about 25 years. Special devices will be used to handle the silicate ores found abundantly in that camp. About 7% was formerly lost in the tailing owing to the lack of adequate equipment.—The Little Boss Mining Co. has developed one of the best mining tracts in Granby during the past few months. A heavy tonnage of ore has been shipped weekly and the ground is developed to the stage where a mill is required. The contract has been let for a 100-ton plant to be erected at once.—A good strike of galena and zinc-blende was made a short time ago on the Miller land, near the Henderson mines. Several drill holes were sunk striking ore from 14 to 25 ft. Drifts are being driven at the 25-ft. level. Four sub-levels have been taken and the ore is being milled in custom plants.

Granby, September 19.

MONTANA.

The Montana Mine Owners' Association has recently sent out a frank statement in answer to criticism regarding its apparently secretive business methods. It says in part: "It may be definitely stated that the fullest information has been at all times furnished to the individual members as to the plans and work being carried on by the officers and executive committee. As to giving general publicity to the work the press and general public must bear in mind that the association, in its efforts to secure more favorable smelting rates, is opposed by trusts of unlimited capital and great experience in the art of business intrigue and diplomacy of the Machiavellian school, and the making public of the plans being carried out would have put into the hands of the enemy the power to circumvent and defeat their accomplishment. "At the time of the organization of the association the conditions surrounding the new smelter located at Ponderay, near Sand Point, Idaho, seemed propitious for the association assuming its control and management and its officers and executive committee energetically entered upon this plan of accomplishing their purpose. The plan of carrying out this plan was not fully realized, a contract was entered into by the association and the Idaho Smelting & Refining Co. under the terms of which the ores of members of the association were to be treated at exceptionally favorable rates, both as to low smelting charges and deductions and penalties. Recently Thomas L. Greenough, the president of the association, and others, have secured a controlling interest in the smelter, and one furnace is now in operation and the second stack will be completed and blown in within 30 days, there being several thousand tons of ore in the bins to supplement the large daily output of the Greenough mines. This new organization has assumed the above contract with the association and its members may now avail themselves of its favorable terms. The successful carrying out of these plans has caused the trust smelters to reduce their charges over 30%, but this reduction does not, by a large percentage, meet the advantages available to the members of this association by shipping their ores to Ponderay.

The inquisitive method employed in the classification of railroad lands under the mining law brought about much uneasiness to mining operators, but the matter has been set at rest through the efforts of the association. The matter of the inequitable charges raised by railroads for the transportation of ore was presented, in form of charges, by the association before the Montana State board of railroad commissioners. The hearing lasted four days, the association being ably represented by T. J. Walsh, of Helena, who generously volunteered his services. The matter is still pending before the board, and there can hardly be a question but that the result will be a readjustment of rates upon a more equitable basis.

Thus far the work of the association has proved of inestimable advantage to the mine owners and operators of Montana and is a guarantee that greater good can be accomplished if all in interest lend their aid to the efforts of the officers of the association, none of whom are, now receiving any compensation for their services.

"Legislation is needed, and can be had upon the demand of the association to properly protect the rights of mine owners and operators against unjust and unlawful encroachments of other interests of far less value to the development of the State."

NEVADA.

ESMERALDA COUNTY.

The Goldfield Con. Mines Co. has decided that no more leases will be given and no extensions of existing contracts granted. The big mill will soon be ready to start, and it is the desire of the Company to do all work by company account. There are 32 sets of looses on the Consolidation mine, and all second and relooses are to be removed by November 1st, until the end of their respective contracts.—Prior & Quinn have been granted an 18 months' lease on the Sandstorm, at Goldfield. The block is an unusually large one, and embraces 500 ft. on the Kruger and 600 ft. on the Magnolia
MEXICO.

The management of El Favor mines at Elatam, Jalisco, is considering the installation of 250-hp. gas producers, to be used until such time as electric power is available. The first section of the mill is to be ordered soon. It will have a capacity of 100 tons. A complete compressor plant has recently been put in at the mine. — The Roosevelt mine, at Guanajuato, has been sold by E. J. Kinkead to W. D. Middough. The mine is south of the Fingano on the same vein. — The Philadelphia Copper & Gold Co., owning the San Vicente mine at Atotonilco, has just finished a 10-stamp mill and concentration plant in place of the present equipment and later a smelter to take care of the ore and concentrate. M. J. Statter, of Philadelphia, is the manager. — Cia. Minera Franco-Mexicana has been organized to operate in the districts of Jalisco and Jalapa, in the State of Vera Cruz. The principal stockholders are Guillermo Voigt and Alberto Schuller. — The San Javier Co., Jocotlan, Son., has recently taken over the Cretan and California mines and is planning to erect a small smelter to make matte. Jacob J. Smith, 159 La Salle street, Chicago, is the manager. — The work of repairing El Cubo mill is proceeding slowly while work on the extension of the adit is being forced. Gerald Reaves, who is manager, says that just as soon as the adit reaches and uncovers a satisfactory ore body, the project of the new plant will be begun. The site for this has been chosen and acquired and the necessary funds are in the treasury of the company. — The little town of Cubo is entirely dependent on this one property, so that the commencement of construction of the new plant will meet with genuine approval of its inhabitants. — C. D. O'Brien, Jr., and H. H. Kenkel, of Minersville, Minn., have taken a bond on the old Carroshas copper mine, in the Ameca district of Jalisco, and will start development at once. In last April H. N. Canol, of Guadalajara, took the mine under bond and lease, and at once installed $30,000 worth of machinery, including a 40-hp. hoist. Mr. Canol sunk a two-compartment shaft for 98 ft., and the new owners will deepen it. — A controversy that has caused a long delay in the plans of the Rosario Mining Co., of the Bolivar district of Jalisco, has been settled days ago by the Department of Fomento in favor of the American concern, and extensive work will now be started. The controversy resulted from denouncements made last year by Faustino Salcedo, the stamp agent at Colotlán, which denouncements covered some of the principal ground of the Rosario company. A protest, accompanied by titles to the same, was made by the Department of Fomento, and finally a decision denying the Salcedo denouncements was handed down. Since the controversy opened no work has been done by the Rosario company.
Special Correspondence.

MELBOURNE, AUSTRALIA.

Financial Reaction.—Large Combine of Metal Producers.—Attitude of Broken Hill Proprietary.—Influence of Labor Party.—Cost of Producing Lead.—Change of Metal-Content of Ores.—Progress in Zinc-Concentration Methods.—Smelting at Port Pirie.

The world of Australia has suffered from financial reaction, and it takes to "groaning" badly. Four years of high-lows, after which people contented and happy, but they now grumble at H. H. Rogers and another who engineered a certain copper deal and then looked on. What they wanted was that the metal market should have been kept booming and that the London Stock Exchange should have stood at fever heat, so that they could have had the delightful experience of our pastoralists, high prices and a big wool clip. However, as the consumer took a hand in the deal to the discomfiture of the copper bulls they now want to be told that purchasing is to be started on a large scale again and that prices are going to soar once more. The decent portion of the press preaches patience and disbelief in statistics of production and consumption of the metals. This comes the whisper that another metal combine is in the air. European lead producers are said to be following the movement Australia is wanted to put in the Broken Hill mines, so it is said, but the big people of the field will want definite and favorable proposals to be made before they tie up their output, though they have decided to be represented at the conference. The Broken Hill Proprietary Co., for instance, has practical control of the trade with the Fair East, and would require a very sound guarantee that sales will be met before they agree to tie up their output, though they have decided to be represented at the conference. The Broken Hill Proprietary men belong to the Mt. Lyell Co. A month ago a Russian concern was stranded in the United States over sales of its blister copper during the copper-market crash last year sets these people against an alliance with any combination, even inside their own territory.

Then the Australian labor party is a factor. It would invoke Federal legislation against restraint of trade should there be danger of throwing miners out of work. No one outside of Australia can realize how parties are swayed to do the will of the labor leaders. Mining men here, however, have measured their strength and know that it will be used without restraint. The mines, as a matter of fact, are virtually owned abroad. That fact, according to British ideas, would convey the right to act as the owners, might think fit. The contrary, however, is the case, for outside ownership is regarded in Australia as foreign and no mercy would be shown. The "new protection" policy of the country aims at passing on to the worker some of the benefits that are supposed to accrue to a country under a protective tariff. New protection is the great plank in the platform of the worker, and trade combinations that fail to recognize it are brought to heel. Why, therefore, should an outside combination escape? There was not a month opened in a short time, as all the Broken Hill mining companies want to review the agreement conceding the employees 12½% increase in wage to the end of 1908. A jump in the price of lead would mean the postponement of that issue, because the men are not likely to consent to go back to the old scale unless they are convinced that work cannot be carried on at a profit.

Recently three big Broken Hill companies have brought out their balance sheets. These are the Proprietary, the South, and the North companies. The figures in the case of the first two are appalling. For the six months ended May 31, 1907, the Broken Hill Proprietary Co. earned over £380,000 net profits. For the same period this last half-year the total is down to £22,750, with 100,000 tons of ore treated. In the six months lead never went below £1, and as the chairman of the Company declares that the Company cannot make a profit with lead at under £1.15s. per ton, it is apparent that a good portion of the profit has come from the sale of zinc concentrate. With the South company, which today claims to be the biggest mine on the Barrier range, the profit was down to nearly £500, and the North company to £17,000, as compared with £36,000 twelve months back. The cause of this collapse is not the price of lead. For during the fiscal half-year of this Company that metal averaged about £1.15s., but lies in the higher labor charges, the extra cost of supplies due to the tariff and, last but not least, the heavier smelter charges imposed by the metal-buyers. These purchases for European smelters, and the latter having grown tired of doing work for nothing, save what was to be made in speculation in the metals, have jumped their charge from 55£ to 95£. Another fact is that, despite the statement published again and again that the metal content of the ore improves in depth, the reverse is the fact. There may be temporary enrichments, but the ore gets poorer in lead, though the change is very gradual. Still, that there is a falling off is unquestionable. In the Block 10 mine, which is working the deepest lift on the field, the sulphide is exceedingly close-grained and hard, and has to be practically slimmmed to ensure decent recovery. The zinc content also is higher.

The great development of the field, however, has been the progress made with the separation of zinc-blende. At the Proprietary the Delprat acid process is relied on, and it gives a 49% zinc concentrate. At the Central mine the Cattermole, an oil and acid process, furnishes a 48 to 47% concentrate, and its rival, the Elmore process, worked by the Zinc Corporation, has achieved a 48% concentrate. More than that, it gets a fair lead and a high silver concentrate by vaning the zinc concentrate from the Elmore plant after flushing off the oil. Near by, also, the De Bavy water-process gets a 47% concentrate at a low cost. There is no doubt that the zinc industry is at last established at Broken Hill, after a decade of the most persistent experimenting. Costs have still to be determined, but that hard fact sticks.

The last additional fact to be told is that the experimenting of the Broken Hill Proprietary Co. with the smelting of
zinc, carried on with one unit at Port Pirie on a working scale, has been successful. The next move of the Company will be to begin the erection of other units. The desideratum is calamine, but even with that absent the European expert is understood to be satisfied that it will pay the Company handsomely to engage in the enterprise.

**MEXICO.**

*Oil Gusher at Ozuluma.—Extinguishing an Oil Gusher on Fire.—Oil Concession in Chihuahua.—Mines at Terrazas Sold.—Veta Coloreda Co., Parral, Re-organized.—Revival of Work at Santa Barbara and Sahuayacan.—Developments in Oaxaca.*

That "tis an ill wind that blows nobody good" has been well exemplified in the case of the gusher oil well of S. Pearson & Son at Dos Bocas, near Ozuluma, about 60 miles south of Tampico in the State of Vera Cruz. On July 4 this well unexpectedly burst forth, blew out the casing, caught fire from the boiler of the drilling machinery, and for two months was a great spectacle. At times the burning oil shot into the air a distance of 1000 to 1500 ft., and as high as 75,000 bbl. of oil may have been consumed every day, so that the total loss to the owners has been enormous. An immense crater, about 100 yd. diam., formed around the mouth of the well, earth was banked around it to prevent the spread of the burning oil, and every known expedient resorted to for checking the flow of oil and extinguishing the fire, but the great heat made it almost impossible. Success was at last attained by the use of powerful centrifugal pumps hurling volumes of water and sand into the centre of the crater, so that the fire has been extinguished, and though the flow of oil continues, immense tanks are being constructed to catch and store it until the hole may be completely closed. When this is accomplished another well will be drilled near the old hole in order to strike the same body of oil. The great force of this gusher has shown the possibilities of the region, and several large companies have entered the field and are endeavoring to obtain ground on which to drill. It has also given an added impetus to oil prospectors in the States of Tamaulipas, Vera Cruz, and Chihuahua, particularly in the recently opened fields of Vera Cruz and the Pichucalco district of Chiapas, and also in Lower California. At this time there has been made public the Government concession given to Alberto Terrazas, of Chihuahua, which conveys to him the exclusive right for a period of years for the exploitation and development of oilfields in the extensive mining districts of Jurubide and Canari, in the State of Chihuahua.

Last week a contract was made on a deal pending for the purchase of the Rio Tinto Mines & Smelter, at Terrazas, 25 miles north of the City of Chihuahua, from Gov. Creel and associates by Corrigan & McKinney, of Cleveland, Ohio. It is now understood that the deal has been consummated and the properties turned over for $187,000 gold. As the new owners have other large interests in Terrazas, and can produce a large tonnage of both lead and copper ores, it is quite probable that smelting operations may be resumed at the Terrazas smelter in the near future by Corrigan & McKinney. The entire work is in charge of R. B. Hutchinson at Terrazas, Chihuahua, Mexico. It is not at all improbable that Corrigan & McKinney may have to take over the Concho mine and mill, in the Ocampo or Jesus Maria district of western Chihuahua, which was sold last year to the Greene Gold-Silver Co., but on which payments have not been completed. Martin J. Condon and associates held the option on the above mentioned Rio Tinto mines and smelter until recently, but forfeited their rights by failure to meet payments because of the financial stringency. Perhaps for the same reason they practically suspended operations on the Veta Coloreda Mining & Smelter Co., of Parral, Chihuahua. They have re-organized the latter Company, and it is understood that ample funds will be forthcoming to resume operations immediately. The Hinds Consolidated Mining Co., at Santa Barbara, Chihuahua, is to resume operation also within the coming month. The visit in the early part of August by the Pittsburg stockholders of the Sahuayacan Mining Co. to the properties in western Chihuahua has resulted in the determination on their part to re-organize, raise the necessary funds for a larger equipment, and resume under the efficient direction of the present manager, George E. Howard, of Sahuayacan, Chihuahua. This will be gratifying news to everyone in this part of Chihuahua, for the past shipments from this property have proved its richness, and it has only been lack of equipment that has prevented the Sahuayacan mines from attaining the position they deserve.

Re-organization seeming to be the order of the day, it is understood that the New York and Boston bondholders of the Oaxaca Smelting & Refining Co., who bought in the Oaxaca plant for $275,000, when it was sold at auction last July, have re-organized and will soon take steps to protocolize in Mexico so that operations at the smelter may be resumed by the end of the year. It will probably be controlled by the Boston interests with H. M. Hobbrook in the financial end at Oaxaca. Boston capital has also entered the Taviche district, and through A. B. Foster has bought the Santa Catarina, on which more vigorous work will soon be initiated. The San Juan de Taviche Co. is preparing to sink its shaft an additional 100 ft. It is believed the affairs of the San Juan-Ejutla railroad, construction on which has been delayed by reason of a mortgaged loan, have been straightened out so as to enable the plans of the company to be pushed to an early completion. Work in the adit of the Humboldt mine of the Commonwealth Mining Co., of Boston, situated in the Ocotlan district, continues to give most encouraging results and a mill will probably be erected on the property early in the coming year. The ores are silver, and a very rich deposit was cut in July last.

Gov. Damian Flores recently visited the Taxco district, and spoke of the great future that promised the smelter of the Cla. Met. de Tultepec, and the concentrator at Atitlanc. In view of the needs of the expanding mining interests of this region the Governor promised that in place of the male trails now existing, a graded automobile road would be made from Taxco to the Narango station of the Cuernavaca branch of the Mexican Central Ry. before the next rainy season, which begins in June. The eastern part of the Julianita mine is now employing over 250 men. Extensive work is also in progress in the Golondrina and Acatitlan mines. A new corporation, organized in Mexico under the name Cedral y Anexas, will develop the Zumpachuxhui mine.

**CHICAGO.**

Illinois and Indiana were favored last week by a visit from the party of distinguished mining engineers now visiting the coalfields of the United States under the guidance of J. A. Holmes of the Technologic Division of the U. S. Geological Survey. The gentlemen were Capt. A. Desborough, H. M. Inspector of Explosives, representing Great Britain; M. Victor Watteyne, Inspecteur General des Mines of Belgium; Herr Conrad Melssner, Geheimer Ober Bergrat u. vertragender Rat im Min. für H. und G. von Prussia; with Messrs. E. A. De Lane Jr., R. T. Chamberlin, and L. W. Mann of the U. S. Geological Survey; and J. M. de Terra Haute, Ind., visiting the Richards mine, in company with G. H. Ashley and E. F. Lines, who are engaged in making the re-survey of the Indiana coalfields. Saturday the party was taken in charge at St. Louis by President G. W. Traer and representatives of the Illinois Coal Operators' Association, and the State Geological Survey, and carried in a series of one day tours to various points along the Illinois Traction Co. A particularly careful inspection was made of the Consolidated No. 14, at Staunton, under the guidance of General Manager Schmick and Chief Engineer Smith, and of the Peabody mine at Sheridan, near Springfield. In the evening they were handomely entertained at the Springfield Country Club, after which they
left for Cardiff on the private car of Mr. Delano of the Wabash railroad. Saturday was spent at the Cardiff mine, the day ending with a dinner at the Chicago Athletic Club, attended by representatives of the State, the operators' association, and the technical press. The party left the same evening for Wyoming and other Western States, to continue their studies of American mining conditions, expressing themselves as highly interested and pleased with what they had seen in the Middle West. It is understood that they are to make a report to the Secretary of the Interior after the trip, and to make recommendations regarding investigations to be conducted at the new Government laboratory at Pittsburgh. The gentlemen made an excellent impression, and it is the opinion of the operators who met them that this co-operation between the testing laboratories of the four countries represented is certain to be productive of far-reaching results, as well as of great economies. As a portion of the same general plan, Geo. S. Rice, formerly of Chicago, but now connected with the U. S. Geological Survey, is spending this summer abroad, studying the methods and results of the foreign stations. He was recently present at a series of coaldust demonstrations at the Altotts (Engeland) station, which blew up timbers and a testing cylinder quite like a regular mine explosion. The coal trade and market continue dull, but in the meantime some of the railway mines are making records in production. The latest claimant to honors of this sort is the Superior Coal Co., of Gillespie, a Company affiliated with the Chicago & Northwestern railroad. The record is as follows:

- **Aug. 24.**
- **Aug. 25.**
- **Aug. 26.**

**Mine No. 1.**
- 3270

**Mine No. 2.**
- 3919

**Mine No. 3.**
- 3501

It should be remembered that this tonnage was hoisted in an 8 hr. day, and that none of the mines is more than four years old. The mines are about 350 ft. deep, and equipped with first-hand equipment. The superintendent, the Lord, has the distinction of having hoisted 2000 tons in one shift from one of these mines within 12 months after breaking ground. One big factor in such operation is the steady work and assured output which the relation to the railway gives.

The effort to find a good coking coal in the Middle West continues. As is well known, the West coals are generally dry and free-burning, besides which they contain too much sulphur to compete with Eastern coal in the coke market. The more careful and frequent sampling and analysis now in vogue has brought to light certain areas within which the sulphur is low, and by washing may be made still lower. Experiments continue with various types of ovens, and it is hardly to be doubted that sooner or later a local supply of coking coal that will at least be usable, if not entirely satisfactory, will be found. This summer experiments have been carried on at Linton, Indiana, and Sesser, Illinois, in both cases, it is announced, with excellent results. At the latter point the work was done by A. W. Belden of the coal-testing plant at Denver, and a very good product has been obtained with but little expense. How seriously this proposition is taken is evidenced by the fact that both the U. S. Steel Corporation and the Solvay Process Co. are known to have purchased considerable holdings of coal land in southern Illinois within the last few years.

Development in the Illinois oilfield is going forward slowly, as a result of the usual over-production. Not even the Standard Oil Co. is able to care for the net production at the rate it was coming in, so that temporarily drilling has almost ceased. While this makes it necessary for some lease and lease holders to postpone for a little the accumulation of a fortune, it is undoubtedly a good thing for the territory as a whole, as it will prevent waste and hold up prices. There are probably a large number of men at work laying a competing 10-in. pipe-line to the east. Small wells continue to be brought in throughout the western part of the State, but nothing of much importance has yet developed.

---

**JOPLIN, MISSOURI.**

**Revival in Prices.—Smelters Resuming.—Developments in Oklahoma.**

**—Change in Leasing Policy by Granby Co.—New 250-ton Concentrator to be Built.—Steam-Shovel Work in Zinc Mining.**

During the past month there has been a revival of mining in the Missouri-Kansas zinc district, due in a large measure to the increased prices of ore, which prices of lead were in excess of $90 for the month, while zinc ore sold upon an average base of $36 per ton of 60% metal. On all grades of ore sold the average price was $2.20 more per ton than that received in the previous month. Zinc ore has sold for $40 per ton the past month, for the first time in many months. Under this stimulus conditions have improved materially. These conditions are largely due to the increased demand for zinc ores through the starting up of five of the different smelting plants in the Kansas, Oklahoma, and Illinois zinc-smelting centres. At Gas City and Iola, Kansas, the smelters have fired up two additional furnaces; at Bartlesville, Oklahoma, two furnaces have been fired up; and at Danville, Illinois, the new plant of the Oak Creek Zinc Smelter Brodhead has been completed and ready for operation. Preparations are also in progress to re-start the Ozark Zinc Oxide plant at Joplin. During the past week all the buying agents for the smelters became active, with the result that ore is now bringing $37.59 per ton of 60% zinc.

These conditions have already been strong enough to work the major portion of the big surplus of zinc ores that had accumulated in the district during the winter. The low prices of last winter and spring. In the district at the present time the total surplus is about normal, or slightly in excess of 5000 tons, all of which is held by strong companies for at least a $42 base. Despite the better tone of the market, however, few of the mills in the sheet-ore belt have resumed operation. Preparation has been made by a number of mills to re-open in the near future. J. W. Thomas, manager of the mill in the Webb City camp, while five new plants are to be erected in the Duenweg field. One of the most important movements in recent months has been the announcement of the Granby Mining & Smelting Co. of a change in its system of leasing lands to operating companies and individuals. Formerly the company pursued the plan of assisting the small lesee to develop a mine by providing machinery and supplies, and paying the lessee $1 per foot for sinking the shaft. This enabled anyone to take up a lease and work it. In return the Company demanded a higher royalty and the option of purchasing all the ores. As the mine became a producer the cost of the supplies and contract price was deducted by installments until the whole cost had been refunded to the Company. In the event the shaft did not strike a paying orebody the Company lost all it had put out and the lessee was exonerated from any financial responsibility to the Company. This system had made Granby renowned as the best poor-man's camp in the district. With the change of policy the Company gives no assistance, but leases to operators upon a straight royalty, and the ores are sold in the open market. Neither are the leases restricted in size, as formerly. This system will have a tendency to crowd out the small operator and to encourage mining on a large scale. All development was previously confined to the shallow deposits, but with larger companies
the deeper orebodies may be taken up. The Grany company is the largest land owner in the lead and zinc region of southwest Missouri. The same Company announced the building of a new concentrating plant in place of the old one which had been in service for over 25 years. The plant is to be a 250-ton mill, modern in every particular, and especially designed to treat silicate ores. The old mill was one of the best zinc-silicate concentrating plants in the district, having a complete sizing system, and old-style Hartz lades. In this plant the capacity was limited to 25 tons per shift, and even then, was a loss of 1½% zinc in the tailing from the mill. The plant did not revolve directly from the ground, but treated those cleaned on hand jacks and sluices. In the treatment the zinc content could be raised to 45 or 47½% zinc.

Another innovation has been the introduction of a steam-shovel for use in the sheet-ground mines of the Prosperity camp. The shovel has been installed in the No. 3 shaft of the American Zinc, Lead & Smelting Co., where it has now been on trial for the past two months. During that time it has shown some good records. All of the machinery on the shovel is armored—protected, in order to save it from breakage when blasting is done in the mines. The boom is 18 ft. long, and the dipper is carried on a novel form of sliding arm. The power is supplied by three belts driven from the boiler, one to raise the shovel, one to push the sliding arm by means of a chain and gear, and a third to revolve the machine and provide traction for the entire apparatus. The shovel is placed upon low wheels with broad tires, and can be moved from place to place by laying boards upon the floor of the drifts to provide a smooth surface. The minimum height of drift in which the shovel will work is 11 ft., while the drifts at the American zinc are 15 ft. The machine requires a full swing of at least 25 ft. These requirements limit the use of the machine, as nearly all of the sheet-ground mines have drifts below 10 ft. in height, and the soft-ground mines are either closely timbered or require pillars closer than 25 ft. The machine takes the place of six shovellers, and requires two men to operate it, an engineer and a helper to break big boulders. The man with a compressed-air and consumes only as much air as is required for two air-drills.

$1,500,000. J. D. Copen, the general manager of the property, owns a large minority interest. The Inspiration is considered by many to be worth the price asked. In all probability it will soon pass to a stronger ownership. The property adjoins the Miami Copper Co.'s holdings, upon which there has been developed one of the most extensive sulphide deposits in the country. The Inspiration is open to the depth of 350 ft. and, it is claimed, has developed 1,500,000 tons of chalcocite ore averaging about 3% copper, and an equal amount of oxidized ore yielding 3 to 4%. The sulphide is found on a contact between Final schist and porphyry granite. Sand is handle the deposit in small particles and seems varying in thickness from a knife-blade to six inches.

The Miami Copper Co. was floated last spring by the General Development Co., which had developed 2,000,000 tons of 3% ore, which, according to J. Parks Channing, the consulting engineer, had been increased by the middle of July to 4,400,000 tons and 2,500,000 tons partly opened up. Since that date the amount of ore reserve has increased to more than 7,000,000 tons. The deposit has been opened on the 270, 370, and 470-ft. levels. On the 470-ft. level the orebody has been opened 1000 ft. along the strike and over 1200 ft. across it. The 570-ft. level is now being opened, and the cross-cut and drifts are in the same character of ore but lower grade than that developed on the levels above. The Miami company is waiting for a connecting road from Globe to its property to begin the construction of the first 1000-ton unit of a concentrator, and because of the enormous tonnage of ore developed, the management has decided to erect the second unit immediately following the completion of the first unit. The General Development Co. has taken over the Newman option on the Keystone group, adjacent to the Miami mine, and has started development work. Chute drifts will be run to the ground to the depth of 600 ft. The Keystone has produced about $300,000 from a vein of silicate ore near the surface. The sulphide deposit has been developed in the Inspiration up to the Keystone side-line at a depth of 350 ft.

The Warrior Copper Co., of whose property little has been heard for some time, is now attracting considerable attention. Under a four-man management the company, those the Black Warrior Copper Co., expended upward of $1,000,000 on the property, most of it in the construction of a plant and other improvements on the surface, including a leaching plant, sulphuric acid plant, and smelter. The surface ores were found unadapted to the leaching process, and the enterprise was a failure. For the past four years E. M. White has been in charge of the property, and has opened a large high-grade orebody on the 250-ft. level of the Montgomery mine. The west cross-cut is in ore for 20 ft. averaging 22% copper, with neither wall in sight; the east cross-cut has gone through 40 ft. of ore that runs about 10% copper. A wind is on in good ore 75 ft. below the level. For three and a half years Mr. White has shipped ore continuously from the Montgomery mine, the returns from which have helped pay for a good part of the development. The Warrior is now shipping 55 tons of ore per day, most of which is taken from the drifts and cross-cuts in the course of development. The Warrior company's original group of claims adjoins the Miami property on the south. The Warrior holdings are the largest in the Globe district, numbering 70 claims.

The Eureka company group of claims, surrounded by the holdings of the Miami, Inspiration, and Keystone companies, and the Berry & Hunt claims comprise one of the best situated and most promising properties in that part of the district. A large amount of silicious ore taken from surface workings on the Eureka returned $250,000 gross. A strong vein of 5% ore has been opened to a depth of 150 ft. It is probable that a drift will be used to prospect the Eureka property. The group of claims owned by the Live Oak Copper Co. adjoins the Keystone on the south. The surface showing on the Live Oak is among the best in that favored locality, and between $600,000 and $700,000 of ore has been mined in surface workings. Boone and Strang, lessees, in 1906 shipped ore from the Live Oak that netted.

GLOBE, ARIZONA.

Inspiration Mine Under Option for More than $1,000,000. — Ore Reserves of Miami Copper Co.—General Development Co. Extending Interests.—Warrior Copper Co.—Eureka Copper Group.—General Activity.

The recovery of copper mining in the Globe district has been so complete that the panic of last October has been almost forgotten. It is no exaggeration to say that Globe has made a greater advance than any other copper mining district in the West, with the possible exception of Butte, Montana. The marked improvement in the Old Dominion mine, and the increased output of copper by that company; the development by the Miami Copper Co. of an immense deposit of low-grade sulphide ore that promises to make one of the great copper mines of the United States; the opening of a very large and high-grade body of ore by the Warrior Copper Co., and the important developments on the Black Hawk fault by the Superior & Boston and the Arizona Commercial Copper companies, explain the expansion of mining here and the greater attention that Globe is attracting in the financial centres of the country.

At the present time a greater number of mining men are here examining properties, who represent large capital seeking investment, than for many months previous. Two large mining concerns are negotiating for an option on the Inspiration mine, and one of them has had experts at the property for two weeks, sampling and assaying the ore. The Inspiration is one of the large copper properties of the Globe district, the control of which is held in Kansas City and Leavenworth by people who have no knowledge of mining, and are without sufficient resources to finance so large an enterprise. Yet they are holding for a stiff price, namely,
MINING AND SCIENTIFIC PRESS

September 26, 1908.

them $290,000. The property is idle at present and will probably be sold within a year. The Orphan Copper Co. is developing a group of claims that lies southeast of the Keystone. A prospect shaft 150 ft. deep has been equipped with a steam hoist and air-compressor, and will be sunk to a depth of 500 ft. before much labor is undertaken. Some good ore has been taken from shallow workings, and high-grade sulphide was recently found in the shaft.

PIOCHE, NEVADA.

Lead-Ores in Demand. — Favorable Smelter Rates on PIOCHE Ores.—

New Plant at Nevada-Utah.— Day Mine to Begin Production.—

Mendah Nevada Mining Co.'s Developments — General Activity.—

Important Discoveries.

Although less ore is going out from here now than was shipped last spring, the camp has made substantial advance. Considerable machinery has been installed and several mines not then sufficiently opened are nearly ready to be worked. Trees in mining situation already. The kind of ore which this camp produces has wonderfully improved. Practically all the mines in the district carry lead, and lead ores are decidedly in demand at the Salt Lake smelters. With the exception of the Boston & PIOCHE, on the old Yuba dikes, every mine now being worked in the region is at present in the limestone. It is a peculiarity of this mining district that the rocks carry all of manganese and iron. As the smelters pay 10 c. per unit for an excess of either mineral, or both combined, and 5c. for limestone in excess, and as lead ore is in active demand, the ores from PIOCHE get a light treatment—charge.

The U. S. Smelting, Refining & Mining Co. has lately been actively in the market for lead ores. The new Tintic smelter, which blends recently, is not now seeking ores here, but is now treating a considerable tonnage of ores which formerly went to the United States Co. or to the American Smelting & Refining Co., and thus making it imperative for them to seek fresh supplies elsewhere. The Steptoe smelter, at Smelter, is already making from 15 to 20 tons daily of blister copper from the product of one and a half units of the concentrating plant. It is the intention to have all young boys in mining situations active, and the copper output will be nearly trebled. It is generally understood that the Steptoe smelter will add lead furnaces to its plant, and enter the market for all classes of custom ore. As a part of this plan, a reliable authority states that arrangements have been perfected for extending the railroad from Goldfield to Ely, and that negotiations are in progress to acquire the line from Ely to PIOCHE. Those who have made the extensions when completed will open up the mines of the entire State to the Steptoe smelter, with much shorter hauls than to the Salt Lake smelters. When Samuel Newhouse was here in May last he was so impressed with the ore resources of this district that he announced his intention to erect a smelter at Bullionville, 12 miles east, where the old mills left 170,000 tons of tailing, in which, Mr. Newhouse is interested. The San Pedro, Los Angeles & Salt Lake R. R. Co. has long desired to establish a smelting plant at Las Vegas, on its line. During the past summer it had experts in the field for months, examining the mines of the PIOCHE district and all the rest of the region from which a smelter at Las Vegas would naturally draw ores. The prospects here are most promising.

The Nevada Utah completed its 300-hp steam plant at the Day mine more than a month ago, and has been sinking vigorously on the Onondoga shaft ever since. The old Onondoga shaft, 500 ft. deep, has been enlarged, straightened, and timbered, and already sunk nearly 100 ft. deeper. In about two weeks more sinking will be completed, and driving begins on the old shaft with higher level. Experts expect to tap about December 1. That will re-open the mine for shipping, which was discontinued about three months ago. The old working shaft near the mouth of the Day cross-cut at the third level, and its antiquated plant, have been permanently abandoned. With the two shafts thus connected by the ninth level, the mine will at once be perfectly ventilated, a condition heretofore seriously lack-

ing. James P. Gaskill, chief engineer of the Nevada-Utah, and Mr. Wickes are confident that with their new plant and a carefully matured system of development and operation already planned, they will be able to put ore into the bins at the Jack Rabbit end of their narrow-gauge railroad for 50c. per ton, and for 25c. per ton more deliver it into cars at the PIOCHE depot for shipment to the smelters, hauling it 15 miles over the narrow-gauge railroad. Mr. Gaskill says it is his purpose to give his attention and energies exclusively to one at a time of the various holdings of the Nevada-Utah. By Christmas the Day should be again producing and, with the new economies, yielding a handsome net revenue from the abundant quantities of ore now in the mine. Prevailing prices for silver and lead. The Company owns what is left of the famous old mines, Raymond & Ely and Meadow Valley, at PIOCHE, practically virgin below the 1200-ft. level, at which point the water-level was found.

The Boston & PIOCHE, which owns a group adjoining the old Yuba mine of the Nevada-Utah on the north, installed in new 100-hp. gasoline plant last September, and has been shipping regularly two or three cars per month of high-grade Yuba East ore. The Prince Consolidated has its new 100-hp. plant in operation. The main shaft is being sunk in shale below the fourth level, while driving is still being done in limestone in the upper levels. The management is negotiating with the smelters for a contract, and there is reason to believe this is the last time this company will blow the plant.

The Mendah Nevada Mining Co. has its new 40-hp. gasoline plant installed and is shipping about 50 tons of ore per week, assaying 25 to 30% lead, 25 to 30 oz. silver, and $15 gold per ton. All the ore has come from development work, practically no stopping having been done in the mine in recent years. The Mendah is one of the old mines of the camp, in which is known as Highvale, Highvale, and has been worked since 1901. The ores occur in bedded veins in limestone at different horizons, these veins being connected by fissures which show a system of block-faulting most interesting to the geologist. The mine was a large producer in the past and gives decided promise for the future. The Ely Valley Mining & Milling Co., about three miles west of PIOCHE, has sunk a shaft on a strong fissure in new 100-hp. gasoline plant. A drill was run for a year and one-half and has not been carried beyond. Fifty feet to the north of the shaft a cross-fissure was found, estimated by Edward Thomson, the manager, to be 25 ft. wide. It is a lead carbonate, and Mr. Thomson says that careful sampling indicates about 40% lead, 16 oz. silver, and $2 gold per ton. The drift south from the shaft at a distance of 20 ft. cut a 2-ft. seam of lead carbonate of about 100 ft. in length. Mr. Thomson intends to sink the main shaft to the 300-ft. level and drive north to the cross-vale. The Ely Valley recently installed a 25-hp. gasoline plant.

About three and a half miles to the southwest, on the PIOCHE Demi-John, a vertical shaft is being sunk in limestone. At 190 ft. a cross-cut entered a vein 40 ft. wide. It is a lead carbonate, carrying streaks of silver chloride and bromide which in places assay over 1000 oz. per ton. The entire body, 40 ft. wide, will apparently pay to ship. It will yield, besides the lead and silver, an average of $8 per ton in gold. The main shaft is now down about 175 ft. This property is equipped with a horse whin, but Owen A. Bailey, of Salt Lake City, the manager, expects to install a gasoline hoist soon after the mine is opened on the 200-ft. level.

The Bristol Consolidated has opened up several new bodies of ore the past summer and has been shipping from one to two cars per week. Several lessees working on this property have also shipped a car occasionally. The Nevada-Den Moines, on the flat in the north part of the town of PIOCHE, which was worked last year by Webster Wheelhouse, has an important new shoot, as reported by finds of high-grade gold ore in cores from a diamond drill, finally got a 40-hp. gasoline plant installed, and has sunk the shaft from the 225-ft. point to the 310, going down four to five feet per day. The highest assay so far has been 95 oz. silver and 49c. gold per ton. The Company is confident of striking a bonanza within the next 100 feet.
Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Blast-furnace slags, as a rule, run a little higher in copper than reverberatory slags produced from the same ore.

Pure silica, or quartz, free from iron, is in some demand for porcelain manufacture. The only permissible impurities are alumina, lime, potash, and soda.

A strong cement for repairing mineral specimens and the like may be made by the following formula: 2 oz. gum arabic, 1½ oz. starch, and ½ oz. white sugar. Reduce the gum arabic to powder and dissolve it in water; dissolve the starch and sugar in the gum solution and cook the mixture in a double boiler until clear. A little gum camphor or oil of cloves will prevent the cement from spoiling.

The stadia is designed to secure rapidity rather than accuracy; but nevertheless, with reasonable care a considerable degree of accuracy may be obtained. The degree of precision is dependent upon the magnifying power of the telescope, the length of sight, and the ratio of the space on the rod corresponding to a given distance on the ground. Using an engineer’s transit with ordinary care, horizontal distances should be determined within an error of not more than 1 in 800 or 900.

Size of wire is ordinarily expressed by an arbitrary series of numbers. Unfortunately, there are several systems, so that it is always necessary to specify the method or wire-gauge used. Wire for electrical purposes is always referred to the so-called Brown & Sharpe gauge, the diameters of the wire being obtained from a geometric series, in which No. 0000 is 0.460 in. diam., and No. 36 is 0.005 in. The Roebbling gauge is almost universally used in this country for iron and steel wire.

Magnesia is regarded as dangerous in cement when in excess of 4%. Many German engineers, however, insist upon raising the limit to 8%. Contractors, generally, are unwilling as yet to accept such material. Magnesian cement will not stand as high a temperature in burning the ‘mix’ as non-magnesian cement; in other words, it suffers more from ‘over-burning.’ Magnesian cements possess a higher coefficient of expansion than normal cements, and show a lower tensile strength. California possesses immense quantities of magnesian limestone which could be utilized in cement manufacture if standard specifications would admit of the use of a product containing from 4 to 6% magnesia.

Organic matter in tailing acts as a cyanicide in so far as the decomposition of the vegetable debris results in the formation of carbon dioxide and various organic acids. The latter may be neutralized with lime. If the organic matter is present in large quanti-

Mining Claims on Forest Reserves.

The Editor:

Sir—Your editorial in the Mining and Scientific Press of August 8 is noted with pleasure. There are several matters mentioned, however, which might give a wrong impression, especially as to the proper functions of forest officers, both in the past and at present. As to mill-sites, briefly, they are necessary adjuncts to proper mining, and this has always been the attitude of the Forest Service. The regulation in the Use Book for 1908 merely places upon record the uniform policy of the past. I believe that the point should be emphasized that claimants are not obliged to look to the Forest Service for their patents. These matters are entirely within the jurisdiction of the Department of the Interior, to be determined according to the laws of Congress. True, as stated by Supervisor Barrett, forest officers make examinations of claims within the forest, but these examinations are merely to gather evidence to present to the General Land Office. Where the claims are apparently valid, there is no need for more than a superficial examination. Your statement, “The chief danger, however, is not from legitimate mining, but from fraudulent application of the mining law to attain other purposes,” shows the reason for the examination. Where the claims are apparently located for fraudulent purposes, they are examined carefully, so that the public may be protected and the actual conditions shown when the matter comes to a hearing, but forest officers can do no more than present the facts in each case. They cannot determine the validity of a claim, nor can the Forest Service. The claimant can present contrary evidence, if such evidence exists, and the matter is disposed of by a judicial proceeding in which the Forest Service has no authority whatever. It is not, therefore, accurate to say that it lies within the scope of the supervision exercised by forest officers to determine its mineral character or to pass judgment upon the validity of a claim. He can do neither. He can collect evidence upon these points, but the law itself is wholly beyond his influence and is the same within and without the National Forests.

I fear that it would be difficult to frame legislation which would define the presence of a valid discovery more adequately than the existing law. Discovery sufficient “to justify a prudent person in the expenditure of money and labor in exploitation” (Christmas r. Miller, 197 U. S., 313), is the rule, and, if properly applied, I believe adequate. The evidence gathered by forest officers, miners, and geologists, is of value in proving or disproving the existence of such discovery, but it is primarily for the claimant to establish the discovery. So far as I am aware there was no serious contention ever made that the old leasing system should be re-adopted. During the recent coal-famine it was very generally agreed that a necessary of life, such as fuel, ought not to be the subject of monopoly, and this opinion still exists, but I do not believe a return to the old system of leasing other mineral lands has ever been actively advocated since it was abandoned.

I greatly appreciate the spirit of your editorial, and am writing, not in defense of the efforts of the Forest Service to secure a compliance with what seem to me to be very reasonable laws, but to dispel, through your assistance, the general impression that there is a separate system of mining laws or regulations for the National Forests. The mining laws for the public domain and for the National Forests are uniform.

A. C. Shaw.

Acting Law Officer, U. S. Forest Service.
Washington, D. C., September 10.

Cyanidation of Silver Ores.

The Editor:

Sir—F. J. Hobson’s account, in the Mining and Scientific Press of August 1 and 8, of the successful cyanide treatment of ores containing the sulphide and sulpho-salts of silver, is of great interest and value, both technically and historically; but his explanation of the reactions involved is decidedly open to question, and some of the equations put forward to support his views seem to be quite incompatible with established facts. An equation ought to express quantitatively a reaction going on between definite weights, or rather masses, of the original materials, yielding products of known composition, but in some cases at least Mr. Hobson has given us formulas representing substances whose non-existence has been pretty conclusively proved, and has accepted feeble and indirect evidence as indicating their presence. I refer particularly to mercurous sulphide and to potassium mercurous cyanide (HgS and KHgCy3). The former of these has been shown to split up, if formed at all, into a mixture of metallic mercury and mercuric sulphide (Hg + HgS). While mercuric cyanide (HgCy3) and potassium mercurous cyanide (K,Hg2Cy3) are well known, and can be readily prepared and crystallized, the corresponding mercurous compounds have not been described, and find no place in chemical literature. A careful investigation which I made some years ago indicated, and the experiments described below, which have been made or repeated during the past few days, will, I think, prove that potassium mercurous cyanide cannot exist in solutions prepared in the manner and under the conditions described by Mr. Hobson.

I believe that the beneficial effects which have been observed to follow the use of mercury salts in cyanide solutions can be sufficiently explained by the well known properties of potassium mercuric cyanide when used in conjunction with free alkaline cyanide as a solvent for the precious metals, coupled with its equally well known efficiency as a precipitant of soluble sulphides. For convenience of reference in discussing them, I have taken the liberty of numbering Mr. Hobson’s equations (on pages 182 to 184 of the issue of August 8) consecutively from 1
to 19: other equations which I introduce are numbered beginning with 21. His equation,

$$21. \quad \text{Ag}_2\text{S} + 4\text{KCy} = 2\text{KAgCy}_2 + \text{K}_2\text{S}.$$  

This reaction is reversible. If we dissolve a fairly large amount of Ag$_2$S in a strong solution of KCy, and dilute it shortly afterwards, more or less of the Ag$_2$S will be re-precipitated, proving that some of the sulphide radical remained in the solution. Or upon adding a little K$_2$S we will also get some silver thrown down as Ag$_2$S, which will re-dissolve upon adding more KCy, and so on. This fact was noted 50 years ago by Beechamp, and is recorded in Fresnuius' 'Quantitative Analysis' under Silver. The reaction has been more recently studied by Berthelot, who found that in dilute (N/10) solutions nearly 100 molecules of KCy were required to balance one molecule of K$_2$S, in order to retain silver in solution, instead of four molecules, as equation No. 21 seems to indicate. To be exact, the equation given by Berthelot as representing the conditions of equilibrium is:

$$22. \quad 96 \text{KCy} + \text{Ag}_2\text{S} = 2\text{KAgCy}_2 + 92\text{KCy} + \text{K}_2\text{S}.$$  

Now this proportion (96 mol. KCy to 1 mol. Ag$_2$S) means that 96 $\times$ 65 parts of KCy are required to dissolve and hold in solution 2 $\times$ 105 parts of silver in the form of sulphide, or 28.9 to 1, if none of the sulphide is oxidized. This value agrees remarkably closely with the ratio 30 to 1 which Mr. Hobson has found necessary in practical work with sands containing silver, presumably as sulphide, as he states that the chloride and bromide require much less.

If the solution containing KAgCy$_2$ and K$_2$S with excess of KCy is exposed to the air for some time and then diluted, as a rule no silver sulphide is observed to form, but thiocyanate (KCyS) can be detected in the solution. No doubt this is owing to slow oxidation of the K$_2$S by oxygen, thus:

$$23. \quad \text{K}_2\text{S} + \text{KCy} + O + 2\text{H}_2\text{O} = \text{KCyS} + 2\text{KOH}.$$  

Equations 21 and 23 together are equivalent to equation 2 as given by Mr. Hobson, and quoted above, but it expresses the fact that the change goes on in two stages, and accounts for some of the soluble sulphides stated by him to invariably occur in the solution, as the latter step (oxidation of soluble sulphides) goes on rather slowly. I may add that large quantities of thiocyanate are found in the solutions obtained in the treatment of certain ores which carry only traces of silver but much sulphide of iron, and that other sulphur compounds, especially thiosulphates (such as CaS$_2$O$_3$) and sulphates, are also sometimes produced in working solutions, apparently by oxidation of soluble sulphides. In order to prevent the interference of the soluble sulphides with

the solution of additional silver, or the re-precipitation of the silver already dissolved, they must be eliminated by oxidation or by precipitation with some suitable metallic compound.

As stated by Mr. Hobson (equation 3), the presence of zinc prevents any large accumulation of sulphide in solution; the reaction is, however, also reversible and incomplete, so that small amounts of sulphide cannot be removed in this way. Silver compounds are more effective, acting by virtue of the reversal of equation 21, which accounts for the re-precipitation of silver which is occasionally observed. It is obviously impossible to utilize them in practice. Lead compounds remove nearly all the sulphide, a soluble alkaline plumbite being usually first formed, in presence of an excess of alkali, which reacts with the sulphide:

$$24. \quad \text{PbAc}_2 + 2\text{KOH} = \text{K}_2\text{PbO}_2 + 2\text{KAc} + 2\text{H}_2\text{O}.$$  

$$25. \quad \text{K}_2\text{PbO}_2 + \text{K}_2\text{S} + 2\text{H}_2\text{O} = \text{PbS} + 4\text{KOH}.$$  

The most effective precipitants, however, of sulphides from cyanide solutions are soluble compounds of mercury, which form the double cyanide K$_2$HgCy, and then react as follows:

$$26. \quad \text{K}_2\text{HgCy}_2 + \text{K}_2\text{S} = \text{HgS} + 4\text{KCy}.$$  

This reaction goes on to completeness, and there is no appreciable tendency for the precipitated HgS to re-dissolve. It only dissolves, if at all, in presence of oxygen or oxidizing agents, and without the reformation of sulphide. In equations 7, 8, and 9 certain reactions have been ingeniously worked out to explain the solubility of stephanite and ruby silver ores. These are probably incorrect in so far as they assume the existence of the mercureous salts above referred to, but the formation of soluble sulpharsenates of calcium and the like (or of potassium or sodium) probably goes on to some extent. These sulpho-salts, however, when brought in contact with double alkali cyanides of silver or mercury, behave precisely like simple alkaline sulphides; for instance, Ca$_3$ (AsS$_3$)$_2$ acts as if it were 3CaS + As$_2$S$_3$ (or, in presence of sufficient CaO, as 6CaS + As$_2$O$_3$), precipitating mercury as HgS and silver as Ag$_2$S, unless a sufficient excess of KCy is present, until all the S is finally removed.

Mercureic cyanide is a salt which in solution fails to give many of the reactions usual with mercureic compounds. This peculiar behavior is explained by its being practically undissociated. It is, however, decomposed by soluble sulphides, and by certain metals, such as zinc or copper. It is well known that mercureic oxide, or mercureic chloride, in the presence of an alkali, when added in excess, will decompose more or less rapidly all other simple or double cyanides, all the cyanogen being finally converted into HgCy$_2$; this being the basis of various methods of estimating total cyanogen in solutions. I have found by repeated experiments that when mercureic chloride is added to a mixture of KCy and K$_3$FeCy$_6$ in a solution of alkaline reaction, the ferrocyanide is

1Bertram Hunt has explained this more fully in your issue of August 28, which has reached me since the above was written. He does not, however, take into account the effect of mass-action, whereby a certain amount of silver is dissolved, even in the presence of sulphides in solution, provided that the cyanide is present in sufficient excess.
unaffected until enough mercury has been introduced to convert all the cyanogen of the simple KCy into HgCyl. That is to say, 130 parts of KCy protect the ferrocyanide until 200 parts of mercuric mercury have been added, according to the equation:

(27) \[ 2\text{KCy} + \text{Hg}^2+ + \text{R} = \text{Hg}^+ + \text{Cy}_2 + 2\text{KR}, \]

where \( R \) stands for an equivalent of chlorine, oxygen, nitric acid, or other radical in some mercuric salt. When a mercuric salt is added in excess of this amount the ferrocyanide is gradually decomposed with the formation of some ferriyamide (sometimes prussian blue), and with large excess it is finally and completely decomposed, all the cyanogen going to HgCy2.

When mercurous salts are mixed with an excess of solution of KCy the reaction taking place is, as admitted by Mr. Hobson in the case of the chloride, of this character:

(28) \[ 2\text{HgCl} + 4\text{KCy} = \text{K}_2\text{Hg}^+\text{Cy}_2 + 2\text{KCl} + \text{Hg}. \]

exactly half of the mercury being separated as metal. But he claims that, in the presence of a sufficiency of a ferrocyanide some other reaction takes place, with the formation of a double mercurous cyaniode, hitherto unknown, no mercury separating, and states that some reducing agent such as the ferrocyanide is necessary to produce this effect. To test this assertion I took the following amounts of material, adding the powdered HgCl to the solutions of the other salts:

(a) 0.192 gm. KCy
(b) 0.25 gm. HgCl (containing 0.212 gm. Hg)
(c) 50 c.c. water.

(b) 0.192 gm. KCy
(c) 0.216 gm. KFeCy6 crystals
(d) 0.25 gm. HgCl
(e) 50 c.c. water.

In both (a) and (b) almost exactly half of the mercury was found in the solution, and half in the form of precipitated metal, as demanded by equation (28). After standing 15 minutes the ferrocyanide remaining in solution (c) was found by titration exactly the same as that originally taken, only a minute trace of ferriyamide being detected. Further, to test absolutely whether the mercury in the solutions containing ferrocyanides could be in the mercurous state, the following solutions were prepared:

(d) To 50 c.c. water 0.5 gm. HgCl was added and well stirred; 100 c.c. of 1% KCy solution was then added.
(e) In 50 c.c. water 2 gm. KFeCy6 crystals was dissolved; 0.5 gm. HgCl was added, and well stirred; 100 c.c. of 1% KCy solution was added as before.

Bertram Hunt (MINING AND SCIENTIFIC PRESS, August 29) points out that, with an excess of HgCl, all the cyanogen combines to form HgCy2. The second reaction he suggests is probably erroneous in showing no metallic mercury deposited, and requiring the presence of oxygen. The following:

(29) \[ 2\text{HgCl} + 2\text{KCy} = \text{Hg}^+\text{Cy}_2 + 2\text{KCl} + \text{Hg}. \]

seems more probable, as metallic mercury is invariably reduced. Even crystallized K,Hg,Cy when dissolved and mixed with HgCl yields metallic mercury:

(30) \[ 2\text{HgCl} + \text{K}_2\text{Hg}^+\text{Cy}_2 = 2\text{Hg}^+\text{Cy}_2 + 2\text{KCl} + \text{Hg}. \]

I have not had an opportunity to test the last two equations quantitatively, but they appear to agree with observed facts.

After stirring 5 minutes, approximately equal quantities of metallic mercury separated in each instance, and were filtered off after standing 15 minutes. Equal portions of the clear solutions were taken in two beakers, platinum electrodes were placed in each, connected in series, and both were electrolyzed. The amounts of mercury deposited on the two cathodes were exactly the same, proving that the mercury in each solution was in the same state of oxidation; whereas, if the first (d) contained mercuric, and the second (c) mercurous mercury, as Mr. Hobson contends, the mercury deposited in the latter case ought to have weighed double as much as in the former. These experiments, which can be easily verified in any laboratory, seem to effectively disprove any claim of the existence of a double mercurous cyanide in such solutions.

Of course, the use of double potassium mercuric cyanide as a solvent or accessory to the solution of gold has been known for many years, having been mentioned by Skey in a New Zealand publication about 1876, and by C. H. Aaron and others in the MINING AND SCIENTIFIC PRESS in 1891; it has also been the subject of patents by Hood and Keith in this and other countries. As pointed out by Skey, when dissolving metallic gold, the action of KCy is accelerated at first by the addition of mercural salts, but retarded later owing to the protective effect of the film of mercury or amalgam produced.

The following is a summary of some results obtained in the investigation before referred to, and may be of interest in this connection. In these tests pure crystallized salts were taken, dissolved in distilled water, and tested with gold and silver foil, with the results stated.

Pure Hg2+Cy2 solution:
No appreciable effect on gold or silver.

Basic Hg2+ cyanide, HgO,HgCy2:
No appreciable effect.

Pure K,Hg2+Cy4:
Very slight action on gold9 if dilute, and cold; slight solution of gold if stronger; more rapid if heated. Mercury is precipitated as gold dissolves. With silver the action is similar but more rapid.

K,Hg2+Cy4, with little KCy:
Action much more rapid, both on gold and silver, than with either salt separately. One atom of metallic mercury is precipitated for two atoms of metal dissolved, whether gold, silver, or copper.

K,Hg2+Cy4, plus equal weight of KCy:
Action very rapid, but more gold and silver are dissolved in proportion to the mercury deposited than with less free KCy. Action becomes slower when a considerable coating of Hg has accumulated. Platinum is also attacked.

Hg2+Cy2 with either KOH, NaOH, NH4OH, or Na2CO3:

9Prof. C. McPhail Smith finds that a small amount of silver is dissolved by HgCy2, and displaces metallic Hg, when spongy silver is used in a hot solution.

9Generally, metal in a spongy condition, such as cornet gold or cement silver, or rolled strips previously deeply etched, was more rapidly attacked than smooth rolled gold or silver, even when the surface of the latter was most carefully cleaned.
Gold and silver dissolved, with deposition of metallic mercury.

HgCl (mercurous chloride), plus K₂FeCy₆, plus excess of KCy:

Solution (after filtering off the metallic mercury which separates) dissolves gold or silver with deposition of metallic mercury.

When either metallic gold or silver is dissolved by any of the above mercuriferous solutions, the effect is probably partly due to replacement of one atom of Hg in the K₂HgCy₆ by two atoms of Au or Ag, which is independent of the presence of oxygen, and partly (if air is accessible) to the action of the free KCy, which is accelerated at first by the influence of the mercury-gold couple thus formed. When Ag₂S is similarly dissolved, this is an exchange of one atom of Hg for two atoms of Ag, the HgS formed being insoluble, and therefore without influence in retarding the dissolving of further portions of silver. There is an obvious economy in mercury lost, when all possible extraction is effected, by the aid of simple cyanide with air-oxidation, before resorting to the use of mercuric salts.

Lead, South Dakota, September 3.

Creosoting of Timber.

The Editor:

Sir—I note your editorial on creosoting of timber in the MINING AND SCIENTIFIC PRESS of September 3. The practice on the Pacific Coast appears to be entirely different to that on the Atlantic. At Norfolk, Va., the timbers are subjected to live steam, then to a vacuum, the dead-oil of tar is allowed to flow in, and is then put under a pressure of 100 to 250 lb., varying with the specification. The Dominion Government and the British Admiralty both had the same specification, and I made the analyses of the timber and of the creosote used for each of them. I should infer from your editorial that the creosote used on the Pacific Coast is fired below 600°. Surely this cannot be so, as the naphthalene and naphtha- lene oils, which are generally considered to be the most important constituents of the dead-oil from a preservative point of view, distil over far below that temperature—in fact, in the presence of moisture, naphthalene will come over in considerable quantity below 212 degrees.

F. H. Mason.

Paso Robles, California, September 11.

'Expert' or Specialist?

The Editor:

Sir—I note that writers in the MINING AND SCIENTIFIC PRESS frequently use the term 'cyanide expert.' Would not cyanide specialist, cyanide engineer, or cyanide metallurgist be better? Cyanide chemist would hardly apply, for, considering the relative progress of the chemistry and mechanics of the process, cyanide mechanic would be more apt. I have been cyaniding eleven years, and call myself a specialist, but I hope some day to be 'expert.' Ojala!

Guanajuato, Mexico, August 28.

Diffusion as a Factor in Ore Deposition.

The Editor:

Sir—It is evident from Lewis T. Wright's communication in your issue of August 22 that I have failed to make my meaning plain in respect of a possible cumulative effect of Soret's principle. In order to make the issue quite clear I will re-state the case, assuming certain ideal conditions, and neglecting those which have not a direct bearing on the question of the efficacy of the laws of osmosis in producing a considerable concentration from a magmatic solution. Let us assume the following conditions:

1. A fluid magma in contact with cold walls; the magma composed essentially of the elements Fe, Mg, Si, and O.
2. Sufficient time for free diffusion.
3. The operation of Soret's principle as stated quantitatively by Mr. Wright.
4. The crystallization of the minerals in the order of their basicity.

Under these conditions, what will be the sequence of the phenomena resulting in a solidified rock? Assuming further that the iron-content of the magma amounts to 20%, I imagine the solidification to proceed along the following lines: At the cooled periphery Soret's principle effects a slight concentration of the bases, and especially of the iron, and when at the contact the temperature shall have fallen sufficiently, Fe₂O₃ will crystallize out, leaving the other elements in solution. In immediate juxtaposition with the now solid magnetite the solution will be depressed below the average content in iron, containing say 10% Fe. Diffusion, however, acting alone, would immediately restore the average content in iron, while Soret's principle would again raise the percentage of iron immediately contiguous to the magnetite to say 30% Fe. On further loss of heat at the periphery there would be a further deposition of magnetite, and the same cycle of changes would occur, consisting in the deposition of magnetite through loss of heat with restoration of the equilibrium of the solution by the operation of ordinary diffusion and the operation of Soret's principle. On the complete solidification of the eruptive we should then expect to find deposited in succession from the periphery toward the centre the minerals magnetite (Fe₂O₃), hypersthenie (Mg₂Fe)SiO₄, enstatite (MgSiO₄), and quartz (SiO₂). That such an ideal succession of minerals should occur in nature cannot be expected, since nature does not operate with ideal simplicity or continuity, and indeed an ore deposit is but a combination of fortuitous circumstances, or, as it has been well expressed, it is "the accident of an accident," and the departure from a regular distribution from the periphery of the Sudbury ore deposits, as cited by Mr. Wright, is readily accounted for by convection currents, varying velocity of flow, and other factors, some of which may be conceived, while others, from the nature of the case, must always remain obscure.

QUARTZ MINES IN COLOMBIA, SOUTH AMERICA.

Written for the MINING AND SCIENTIFIC PRESS

By F. F. SHARPLESS.

It is evident that Colombian placer deposits continue to attract more and more Americans every year, while interest in vein mining is apparently not receiving the attention which conditions in that country warrant. There are obvious and natural reasons why this has been the case, but there are no obvious reasons why it should continue to be so. For years Colombia has maintained a small but constant output of gold, chiefly from its alluvial territory. Realizing this, it is only natural that foreigners should have investigated deposits of this nature, rather than those which have been less productive.

The reports of engineers have not been uniformly optimistic. They have found, in many cases, a gold content of considerable importance, a quantity that in many localities would be attractive; but they have found also that operating costs would be far in excess of those in countries more favorably situated. Yet there have been enough favorable reports from competent authorities to assure us that there are many districts in Colombia where, with a reasonable amount of money, and intelligent management, satisfactory returns may be expected. Hence it is quite reasonable that public attention should be drawn in this direction.

A much smaller proportion of the exported gold has been derived from vein-mining than from placers, yet a small amount of native and foreign capital has been invested in legitimate operations for many years, and on the whole has given quite satisfactory results. The bonanzas opened have, in most cases, been worked by natives; they have not been advertised in foreign countries, and have attracted little or no outside interest; so it is natural that veins now receive but scant attention. Colombia as a whole is not well explored; there are vast areas which are practically unknown, where the lack of transportation and population render exploration difficult and tedious. A comparatively small area is well populated, and where the population is fairly numerous, moderately good trails exist, and there is no difficulty in prospecting when one grows accustomed to the native food. Such districts, however, are already quite thoroughly prospected, and it will be found that the natives are working the veins after their primitive fashion, or at least that they know of their existence.

The State of Antioquia, because of its geographical position and rather numerous population, has been more thoroughly prospected and developed than any other. Within its confines are several well-built mills where modern methods are in vogue, but by far the greater number of properties are worked with native Colombian mills and with Colombian methods. The Colombian mill is the offspring of the old Cornish stamp-mill. It is always built near the water, where power can be furnished by an overshot water-wheel keyed directly to the cam-shaft. The stamps, generally four to a battery, consist of a wooden stem about 5 by 6-in. section, bound with iron at the bottom, and furnished with a square iron shoe. The dies are of cast-iron, or oftener consist of the hardest available rock, well set in the mortar, which is built up of plank. The screen is of loosely fitting wooden slats, or a board with numerous nail-holes. The stamps are raised by wooden pegs driven into the cam-shaft, and drop ten to fifteen times per minute. The capacity of a battery is from 1 to 2½ tons per 24 hr., crushing so that the greater part will pass a 20-mesh screen. The crushed material passes over blankets or burlap, which collects the gold and sulphides. The concentrate is washed in bateas to recover the free gold, and the heavy tailing from this washing is generally ground in small arastras, and the fine material again treated in the batea. At this work the natives are expert, and it is a pretty sight to see the gold creep up the side of the batea in a clean wide band, free from the heavy sulphides, which are thrown away as valueless.

Many veins are being worked by this simple method, which would yield little or no profit to a foreigner with an expensive mill. With two or three miners, a couple of boys to carry the ore, and two women to operate the mill, each taking for his or her wage a small portion of the daily clean-up, and with a mill costing only $150, it is not possible to lose much on the investment, and the little that comes to the owner is nearly all clear profit. Larger properties are equipped with more stamps, some having as many as eight or ten batteries, arranged tandem down the hillside, so that the same water, used over and over again, serves several mills. It is in those larger properties, some of which are now worked, where new capital and modern machinery might be employed to advantage. So far as transportation goes, the placers on the lower rivers have the best of it. There are few railways in the country, and those that exist are of little assistance to the vein-miners. As regards climate and healthfulness of situation, the quartz properties have by far the best of the situation. One of the most serious disadvantages of operating in Colombia is the hot moist climate of the low-lands, where the carelessness of both native and foreign laborers is sure to result in much sickness and loss of time. At an elevation of 2000 ft. the climate is much better; while at 4000 ft. it is delightful. Owing to the scanty population, the heavy tropical growth, and moist climate of the low-lands, and the few rock-exposures, there are not many veins known below an elevation of 2000 ft. During a recent visit to Colombia I spent nearly a year in the States of Antioquia and Tolima, examining quartz veins, and nearly the entire time was spent at an altitude of more than 3000 feet.

The Marmato mines in the State of Cauca have been worked to a greater or less extent since the middle of the sixteenth century, so says Vicente Restrepo in his 'Minas de Oro y Plata de Colombia.' During my visit an English company, The Western Andes Mining Co., was working these properties, milling about 100 tons daily. At the present time the method of working is practically the same as for many generations past. The crushing device
is more modern, consisting of 40 locally-built California stamps, but the concentrators, burlap, blankets, and scratched plank are the same as used for many years. The concentrate is handled in the customary manner, that is, the free gold is removed by means of the batea, while that in the sulphides

concentration. Fluxes are at hand, and good coking coal is within a short distance. Either copper or lead can be used as a collector; though not abundant, both are found in the immediate neighborhood in small quantities. Zinc sulphide is available in plenty, being of that variety known as marmatite, a

is lost so far as the Company is concerned. As a matter of fact, the concentrate is caught by natives on the hillsides below the mine, in small stone-walled enclosures or ponds, where it is allowed to rust for some time and then re-erushed by hand, and again washed in the batea, giving up a little more gold.

The Company's proportion was very small when I was on the property, being between $2 and $3 per ton milled. The quantity recovered after oxidizing is not stated, but an experiment conducted by the English company, and my own observation as well, suggest that as the workings are now entirely below the oxidized zones the ore should be smelted. Some portions can be smelted direct, others would require
day be, the business will be conducted at a handsome profit.

The Zancudo mine at Titiribi has been smelting its ore for over fifty years, and at times has paid handsome dividends, in spite of the fact that its collecting medium, lead, has always been imported from England. To offset this heavy expense, the smelting furnaces, within a mile of the mines, are only a
stone's throw from an outcrop of good coking coal. Unfortunately the owners are not taking full advantage of their opportunities, for the coke, which is made in open heaps and with a high percentage of ash, is costing about 48 cents per ton, when it should be low in ash, and cost not over 42.50 cents per ton.

My investigations did not go so far as to prove positively that there is a good field for a smelting business in Colombia outside of Marmato and Zancudo, but I found galena and copper sulphides at many points, and at almost every little Colombian mill I found concentrate, discarded as valueless, that would be worth smelting could it be delivered to a smelter without too great expense. Several mines, producing a fair tonnage of sulphides, are shipping such product to the United States, and in spite of the heavy freight charges the operation nets a very fair return.

It would be well for those now going into the country with the object of investigating the possibilities of placer mining, to bear in mind the fact that the country is rich in promising veins, and when opportunity occurs it may not prove time lost to look at some of those of which they are sure to hear from the natives. There is undisputed evidence of Colombia having produced many millions of gold, and every probability that it will produce many more.

Repetitive loading of reinforced concrete beams has recently been the subject of investigation at the Materials Testing Laboratory of the University of Pennsylvania. The following conclusions were advanced in a paper read at the June meeting of the American Society for Testing Materials by H. C. Berry:

1. That the ultimate strength of a reinforced concrete beam is not materially affected by one million repetitions of high working stresses.  
2. That the maximum deflection is not affected.  
3. That hairline cracks become visible for such loads at intervals of 6 to 8 in., and grow deeper as the number of repetitions is increased, but that for one million repetitions no crack extended beyond the neutral axis.  
4. That the bond between the steel and the concrete is not appreciably affected, as shown by the difficulty with which the steel was removed in breaking up the beams.  
5. That the position of the neutral axis is not changed by repetitions of the load.  
6. That the greater part of the set in the deformation in the plane of the steel occurs in the first few thousand applications of the load.  
7. That the set in the deformation on the compressive side of the beam is also relatively large for the first few thousand repetitions, and that it increases with the stress applied and the number of repetitions.

A phenomenal series of alloys has lately been experimented with in Germany, consisting of iron with either cerium or lanthanum. These alloys emit a shower of sparks on being struck with a piece of steel. The sparks will ignite gas, or cotton wicking saturated with alcohol, and will also explode black powder and other explosives. The ‘sparking’ property of the alloy reaches a maximum with about 30% iron.

AGITATION BY COMPRESSED AIR.

Written for the Mining and Scientific Press  
By F. C. Brown.

Now that the method of agitation in tall tanks has been adopted by many progressive companies, the following notes on New Zealand experience will be appropriate. The tanks go under the name of the 'B. & M.' tanks (Brown & McMiken) in New Zealand and Australia, the 'Paehne' tank in Mexico and the United States, and Brown's circulating-tank in other countries. In appearance they are cylindrical, but internally they consist of a large cylinder terminating in a cone of 60° slope. The weight of the tank and its content is transmitted by the continuation of the cylindrical shell, stiffened by horizontal angle-bars to a heavy angle resting upon a concrete foundation, as shown in Fig. 1, which represents the tank in sectional elevation. The lower end of the cone is closed by a heavy cast-iron bottom, which rests upon a concrete foundation and takes a portion of the weight of the tank. A doorway in the lower part of the shell gives access to the space around the cone, and a manhole in the latter facilitates inspection of the valves when the tank is empty. The discharge of the contents, after agitation, takes place through a pipe near the bottom, provided with a valve or cock. In the centre of the tank there is a large pipe held vertically in position and open at both ends, the lower end reaching to within about 18 in. of the bottom of the cone, and the upper end terminating about 18 in. from the top of the tank. Means are provided for admitting compressed air into the lower end of this pipe in the same manner as with an air-lift.

Tanks large enough to treat charges of 125 tons are now in successful operation, and there is no reason why even larger ones should not be used. In Fig. 1 is shown the style of tank used at the Grand Junction mine, Waihi (13 ft. diam. by 55 ft. deep), complete with its internal fittings, and standing on its foundation, which consists of a ring of concrete, with a square block of concrete in the centre to support the casting at the bottom of the tank.

Fig. 2 shows the arrangement of jets for a very large tank, or for one in which it is required to treat concentrate or sandy material. There is an opening in the stand of the tank about 3 ft. 6 in. high by 2 ft. wide (Z, Fig. 1), and opposite this there is a manhole (M, Fig. 1). The cone is finished off with a heavy casting (J, Fig. 2) and has a discharge cock. K. B is the central pipe. C the outer air-pipe with a rubber valve, H, at its lower end, D the inner air-pipe with a rubber valve, G, at its lower end, and E, the pipe to supply the solution, water, or air to the distributor, F, which discharges through the pipes I and J, fitted with rubber valves (Fig. 1 and 2). Pipes C, D, and E are supplied with air from pipe O, and with water or solution from pipe N, with the arrangement of valves as shown. There is a circular piece of iron plate serving as a splash-cover to the central pipe B, and this is fastened to the pipe D in such a manner that its height can be adjusted. P is the pipe to supply the slime or battery pulp. This pipe, P, branches
into two pipes, $P^1 P^2$, which are carried along the two rows of tanks. The air and solution pipes are arranged in the same way. $R$ is a platform which runs between two rows of tanks, and from this all the valves can be readily reached. There is a hose attached to a pipe, which goes direct to the filters.

result that the pulp is softened and is readily lifted through the central pipe. The initial air-pressure has to exceed that of the column in the air-lift, but when circulation has been established the pressure can be considerably reduced. The conditions for cyanide treatment are perfect, since every particle

This hose is used for discharging all the tanks, as they are discharged one at a time, and can be moved from one to the other.

The method of operation is very simple. The tank being filled with ground ore and solution, air is admitted through the pipe $D$, which, mixing with the pulp in the central pipe $B$, lightens the column inside of the ore is constantly coming into contact with the solution and air as they enter the bottom of the air-lift. Sand can be treated as readily as slime, and there is no danger from interruption of the motive power, so disastrous in mechanical agitation when sandy material is being treated, as, even after weeks of standing, the contents of the tank can be readily

and causes it to overflow, while fresh pulp is drawn in at the bottom, and is in turn brought to the top, thus producing a perfect circulation, which is kept up as long as the supply of air is admitted. Should the pulp have settled, or should it become firmly packed at the lower end of the air-lift, solution or air, or a mixture of both, is forced in through the jets $I$ branching from the distributor $F$, with the started up, and in less than an hour the whole charge be brought into perfect circulation.

The first large tank was erected early in 1902 at the Komata Reefs Co.'s battery, at Komata, New Zealand. Its dimensions were 7 ft. 6 in. diam. by 37 ft. high, including the cone, the angle of slope of which was 55°. Before deciding to erect this, numerous experiments had been made in a small testing
tank of 20 in. diam. and 8 ft. high, and the results were highly satisfactory. Later on in the same year two larger tanks were erected, their dimensions being 10 ft. diam. by 39 ft. high. These tanks were used for treating slime, and, owing to their great depth, were found to be excellent for the final settling of slime in the decantation process, as they made it possible to decant a large percentage of the solution before finally discharging the treated material. These first tanks were not arranged with the large central pipe and jets for flushing the cone, and it was not until these important features were introduced, early in 1904, that the tall tank became an all-round practical apparatus for the agitation of battery pulp, fine concentrate, and slime. In 1903 an attempt was made to agitate finely ground sand (90% through 200-mesh) in tanks 10 by 39 ft., without the central pipe, but it was found that, although the agitation from the top of the tank appeared to be quite violent and efficient, the compressed air was working its way up through the body of the fine sand without properly agitating and mixing it. Samples of solution taken at different depths in the tank showed different values, and it was found that a large quantity of sand adhered to the sides of the cone at the bottom of the tank and was not agitated at all. The introduction of the central pipe and the arrangement of jets for flushing the sides of the cone with compressed air or solution during agitation, made the tank a success, and it is now, without doubt, the simplest and most perfect agitator known. Seeing that ore-treatment by the cyanide process is becoming a matter of very fine grinding and agitation of the whole product as "slime," an agitator that does its work properly, has no wearing parts, and never goes wrong, will be appreciated by mill-men.

The evolution of the tall tank as an agitator did not come without effort. Like most good things, it required thought, experiment, and money. As already stated, it was first used at Komata, and S. D. McMiken, the battery superintendent, did good work in assisting to make it a success. Later on, when the central pipe was introduced, J. R. Noble and J. A. Thomson, of Waiki, gave valuable suggestions. Now that the tank is perfected, it seems very simple.

In treating very fine material, such as slime, a comparatively short tank will do good work, but as a general rule it is advisable to have the height about 4½ to 5 times the diameter, and height is especially necessary when it is required to treat coarse material or concentrate. It is economy to build the tanks high, as the same size of air-compressor, working at a slightly higher pressure, will supply air for a larger tonnage of ore; also because the cone, stand, and fittings remain the same, irrespective of height. It has also been found that the higher the tank compared with the diameter, the less is the power required for agitation, and tests show that the consumption of cyanide is less in high tanks than in low ones, due to the fact that with high tanks the quantity of compressed air per ton of ore is less than with short ones, though its pressure is greater. The diameter of the central pipe should be about 1½ in. for each foot of diameter of the tank.

The following figures relating to the air and power required are from actual working conditions extending over long periods, ranging from 6 to 18 months:

1. A tank 7 ft. 6 in. diam. by 37 ft. was used for treating slime, and required from 4 to 6 cu. ft. of free air per minute, at a pressure of 22 lb. per square inch. The charge of slime was 15 tons (dry weight), and the horsepower was from one-third to one-half.

2. The same size of tank, treating finely ground concentrate, requires 15 to 20 cu. ft. of free air per minute, at a pressure of about 26 lb. per square inch, this quantity of air gives a thorough agitation with a charge of concentrate of 35 to 40 tons (dry weight), with 1½ to 2 horsepower.

3. An installation of 10 tanks, each 10 by 39 ft., treating slime, requires 88 cu. ft. of free air per minute, at a pressure of 23 lb. per square inch. Each tank holds a charge of 35 tons (dry weight), and requires 3½ hp. per tank.

4. Two tanks, 13 by 55 ft., treating slime, require 32 cu. ft. of free air at a pressure of 33 lb. Each tank holds 110 tons dry slime. The horsepower consumed is 1¾ per tank.

When I first commenced experimenting with these tanks the probable heavy consumption of cyanide due to the action of the air used for agitation was held by some to be opposed to their success. The installation of 10 tanks, each 10 by 39 ft., at the Komata battery has been in operation for 18 months, and although there has been no opportunity for actually comparing them with the usual shallow agitator, it has been found that the consumption of cyanide is very small. At the Grand Junction mine (Waiki) are three different types of agitators, the usual shallow agitator, tall tanks, and a shallow agitator operated by a high-speed screw-propeller, and careful tests have been made, with the result that it has been proved that the consumption of sodium cyanide by slime treated in the shallow mechanically operated agitators during a period of over two months has averaged 2.6 lb. per ton. The consumption by slime treated in tall tanks (13 by 55 ft.) during the same period averaged 2.4 lb. sodium cyanide per ton. Expressed in terms of potassium cyanide these consumptions work out at 3.38 lb. per ton in the shallow agitators, and 3.12 lb. in the tall tanks. The consumption of sodium cyanide by concentrate treated during a period of two months in the agitator operated by a screw-propeller was 3.1 lb. per ton, while those treated in the tall tanks (7.6 ft. 6 in. by 37 ft.) during the same period consumed only 2.4 lb. per ton. These consumptions expressed in terms of potassium cyanide are, 4 lb. per ton in the shallow agitator and 3.1 lb. in the tall tanks. Potassium cyanide is now being substituted for sodium at the Grand Junction mine, as it is found that the former stands the action of the air better, and will effect a considerable economy.

It is not claimed for the tall tank that it increases the extraction. It is simply a perfect agitator—a statement which cannot be correctly applied to many of the shallow types of agitators at present in use.
At the Grand Junction mine, tall tanks compared with the screw-propeller shallow agitator in treating concentrate shows identical results as far as extraction is concerned, but compared with the shallow agitators with arm stirrers in treating slime they give tailing which averages 10d. lower per ton. These tanks are installed at the following properties, namely, Komata Reefs Co., which was the first to adopt them, having a battery of 10 tanks, 10 by 39 ft., treating slime; the Waihi Gold-Mining Co., 23 tanks, 6 by 15 ft., treating concentrate, and 32 tanks, 12 by 38 ft., treating slime; the Waihi Grand Junction Co., 6 tanks, 13 by 39 ft., treating slime, 6 more under construction, and 4 of 7 ft. 6 in. by 37 ft. for concentrate; and the Waihi-Pacrao Gold Extraction Co., with 9 tanks, 10 by 39 ft., treating finely ground sand.

The importance of this agitator in the Waihi and neighboring districts can be readily understood when the nature of the ore is taken into consideration. It consists of a quartz-gangue with some calcite, iron pyrite, galena, and zinc blende, throughout which the gold and silver are exceedingly finely disseminated, the former occurring chiefly as an alloy with silver in about equal proportions, and the latter as mixed sulphides of silver. The proportion of gold and silver in the ore is about one part by weight of gold to six of silver. If a high extraction is aimed at the ore has to be ground to the finest possible pulp and kept in agitation with a fairly strong cyanide solution (about 0.3%) for a period ranging from five to eight days. The concentrate, constituting 8% of the ore at the Grand Junction mine, before being re-ground will all pass a 200-mesh sieve, and the aim of the re-grinding, which is done in a tube-mill, is to bring it to such a fineness that it will pass a silk cloth corresponding to what would be a 400-mesh sieve. This degree of grinding can be brought about if collected concentrate be ground in connection with about 25% of 10-mesh sand, which latter is, by a special separating device, taken from the battery launder. The re-ground concentrate is then agitated in tanks 7½ by 37 ft., holding 40 tons each, for a period of 12 days in 0.4% KCy solution. The value of the concentrate will average £11 per ton before treatment, and the residue comes out at 17 shillings per ton, equivalent to an extraction of 92.3%. This is the average extraction at the Grand Junction mine for the past nine months, where 300 tons of concentrate per month, obtained from 4000 tons of ore, is treated.

'Blowing up' is one of the accidents to which deepwater divers are most liable. When a diver is crawling on the bottom with his head down, air may accumulate in the back of his suit, and, getting to his legs, cause him to 'turn turtle' and shoot helplessly upward, with the risk of coming into contact with a ship's or boat's bottom. To prevent such accidents, the diving committee of the English Admiralty has recommended that all new diving suits be provided with an arrangement for lacing up the legs and thighs.—*Compressed Air.*

An incombustible insulating substance has been recently invented by a Bavarian electrician, which, it is said, will withstand for some time the effect of an electric arc. It is made as follows: mineral pitch is dissolved in a volatile solvent (benzine), and this solution is used as a medium for making a paste of finely crushed asbestos, which is afterward compressed and slowly dried at a low temperature.
SURFACE EFFECTS OF THE CAVING SYSTEM.

Written for the MINING AND SCIENTIFIC PRESS
BY LUCIEN EATON.

The theory of the 'dome of equalization' is very interesting, in view of the theoretical possibilities involved in the matter of the calculation of the size of mine timbers. Unfortunately, the application of the theory of this dome of equalization is extremely limited, for the existence of the dome depends upon the homogeneity of the rock over the opening, and the absence of special lines of weakness; and, as faulting almost invariably accompanies ore deposition, special lines of weakness are almost invariably present, so that calculations of dome-structure become guess-work. And it is easier to guess the size of the timber that will serve than the weight of the 'back' under the dome.

The capping over a caved stope, where the break has not gone through to the surface, often does not fill the entire opening, a vacant space remaining between the arch of the back and the broken rock below; but such cases are relatively rare. They are possible only when all conditions are favorable. If the stope, when finished, is approximately of the shape of the dome of equalization, very little rock will slab off, and the unsupported opening will be large. I have run across several instances of this character, some where the timber has been left standing, but not touching the walls or back of the opening, and others where the timber has rotted out and fallen away. But if the stope is wide and flat, the broken rock from the back will fill the opening before it assumes the shape of the self-supporting dome. Somewhere between these two extremes there is a mean, where the amount slabbed off will just fill the stope plus the cave above, and the back will be left in the shape of the dome of equalization. But disturbing factors are so great and so numerous that correct calculation of the amount that will break down is out of the question.

The effects of caving are as varied on the surface as they are underground. When a stope caves, and the dome above it runs up into sand or loose rock, the depression formed is usually in the shape of an inverted cone; but where the orebody is wide or deep below the surface, the subsidence usually takes the form of terraces. Sometimes comparatively large areas will break through cleanly and the whole surface will drop through suddenly and as a unit, but this is exceptional. After the back has once started to cave, the surface usually sinks in terraces, all drawing over toward the original break. The direct influence of faulting in defining the limits of the surface-subsidence is often, though not always, very clear. Large areas sometimes sink bodily, or in terraces, although only partly undermined, the limits corresponding exactly with known lines of faulting.

A description of the different results of caving at a mine where the occurrence of the ore was unusually uniform may furnish data of interest to men not familiar with the caving system. The mine in question is on the Gogebic iron range. The ore deposit consisted of a lens of soft hematite about 40 ft. in average width and 150 ft. high, with a length of nearly 1600 ft. on the incline, lying in a trough formed between a dike of diorite and a thick band of ferruginous slate, which has been a zone of extensive faulting parallel with the formation. The dike cuts across the formation, dipping southeast at an angle of 45°, but is cut off by a fault along the face of the slate. The slate dips at an angle of about 70°; N. 25° W., which is the regular dip of all the formations, except the dikes, at this point on the range. The trough in which the ore lay pitches northeast at an angle of 11°. Above the dike the formation next to the ore on the north side is a fissile, red slate, richer in iron than the foot-wall slate, and commonly called the 'red slate hanging,' but the actual hanging wall above the ore in the plane of the formation is hard jasper.

It is probable that there has been some movement parallel with the formation in the 'red slate hanging,' as this has been observed in other parts of the range, but it has not been nearly as great as that in the foot-wall slates. In addition, at about 200-ft. intervals, small cross-faults dislocate the formations a few feet.

The deposit was originally mined by square-set rooms and pillars, about 60% of the ore being taken from the initial openings. Some of the pillars were robbed before the hanging caved, and, after this occurred, much of the crushed ore from the pillars and floors was mined by sub-levels and the caving system, especially in the upper part of the deposit. There remains a mass of broken ore and timber, mixed with rock, some of which came from the hanging wall, and some from old square-set rooms that had been filled. On the surface the effects of the mining operations are not uniform. In the western and upper portion of the deposit the back broke through to the surface, running down much of the sand and gravel which covers the lode everywhere here to a depth of 25 to 30 ft. This breaking down of the hanging continued east to a point where the height of the ore deposit and the thickness of the capping were approximately equal, a point which coincides very closely with one of the cross-faults. East of this point the hanging wall has settled bodily, from nothing up to 15 ft., the greatest subsidence being on the foot-wall side and at the west end, near the cave that broke through, and diminishing toward the north and east as the thickness of the capping increases. The whole mass of the hanging wall has slipped down along the foot-wall slate, and has cracked along the red slate on the north, although the movement has not been great there. The east end of the subsidence is marked by a small crack which corresponds to one of the small cross-faults. On the north side of the limit of the cave, where it came through to the surface, is a plane between the vertical and a line perpendicular to the formation; but where the whole hanging has settled, the north limit of the movement on the surface lies approximately over the orebody for its full extent. Underground the whole hanging wall, east of the break that reached the surface, has settled about 75 ft., approximately half the height of the original orebody, and the highest point of the orebody is now along
the north side, whereas it was originally highest along the foot-wall. The capping caved first on the foot-wall side, where it came together with the foot-wall over the ore, and most of the openings seem to have been filled from that side. The caving seems everywhere to be intimately connected with lines of faulting, any tendency to form self-supporting domes or arches having been entirely overcome.

The following figures will give a good idea of the proportions of the ore-extraction to subsidence on surface:

<table>
<thead>
<tr>
<th>Description</th>
<th>Volume</th>

</tbody>
</table>

The first of these ratios is very near the proportion frequently assumed in the iron country, namely, one cubic foot of caving on surface to every three feet of ore hoisted. I know of no other subsidence of the hanging as a whole, where the relationship of volume has been worked out. It seems probable that the proportions will vary substantially according to the relative amounts of capping and ore.

**Shaft-Sinking on the Rand.**—In a paper read before the North Staffordshire Institute of Mining & Mechanical Engineers, and reported in The Iron and Coal Trades Review, Alfred Redfern describes some interesting features of deep shaft-sinking on the Rand. The deeper shafts are of rectangular shape, timbered throughout, and divided into seven or eight compartments. Timber was the best medium for securing the sides in rectangular shafts. It was most expeditious for fixing, as both sinking and timbering operations were carried on simultaneously. It also had a long life of service, Rand conditions being exceptionally favorable, and the shafts being fairly dry, and the sides usually strong ground. With good workmanship, and when treated with creosote or other preservative, the timber would last the whole life of a mine. The water had a preservative rather than a destructive action, and it was rarely necessary to renew the timber by reason of ground movement or weighting. The general arrangements were six hauling or winding compartments 5 ft. 6 in. to 6 ft. 6 in. square, one pump and power transmitting compartment of the same size, and a ladder-way 3 by 6 ft., with platforms 18 ft. apart vertically. The latter was compulsory under the Transvaal Mines Act, in mines having only one outlet to the surface. After sinking was once started, it was proceeded with continuously, without stoppage for week-ends or holidays, except in case of accident or breakdown, each 24-hr. day being divided into three shifts of eight hours each. Each gang consisted of two whites with about 80 natives, and each chargeman fired his respective blast, or round of shots, at the end of his shift. The explosive used was blasting gelatine, averaging a little over ½ lb. to each hole. The cartridge was 7½ by 4½ in.; the detonators were No. 6 and 8, fired with safety fuses, cut in 8-ft. lengths, three to a ring or coil. When all the holes, usually 50 or 60, were charged, torch lamps were lighted, and one white man ascended in the bucket to the lighting stage, switched off the current, and wound up the cable and lamps. The chargeman instructed his assistants as to the order in which the fuses must be lighted, and gave the word, 'fire'. The chargeman lighted the centre row of sumpers, and took care that the others did not get in front of him in lighting the side holes. On the coolness and dexterity of this lighting the success of a blast often depended, for if each shot was lighted in proper order the stone was released in definite and pre-arranged sequence, and with the maximum effect. It was a good practice to burn a warning fuse, that was, a fuse of equal length to those used in each charge, and hung over the side of the bucket. It was lighted immediately before the first shot, and from its rate of burning, warning might be given by the 'boy' left in the bucket to hold the signal wire. The chargeman was the last to travel the length of the shaft, noting if all the fuses were burning. He then climbed into the bucket and gave the final signal, 'clear'. The relieving chargeman usually met the men coming off at the shaft-mouth, and together they counted the reports as the charges exploded, and checked them with the holes drilled and charged. When satisfied that all charges had exploded, the two white men, with several of the most experienced 'boys', descended to lower the electric cables and lamps, and after the sides were trimmed of loose-hanging rock, 'lashings' was commenced, and occupied 2½ to 3½ hours. Drilling was then begun, and the winding engines and all buckets were used by the timbersmen. While 'lashings' was in progress, the timbersmen were occupied in blocking and wedging sets. Where sufficient cheap labor was available, hand-sinking compared favorably with machine-sinking, both as regards economy and speed.

A novel temperature indicator for hardening steel has recently been introduced by an English firm. Its utility is founded upon the fact that when carbon steel is heated to about 730°C, it becomes non-magnetic, and fortunately this temperature is the best point at which to harden tools. The indicator consists of a permanent magnet, shaped conveniently for holding in the hand, its poles being prolonged by rods of special metal, which remain magnetic at temperatures higher than the hardening temperatures of carbon steels. A small object is held upon the fingers of the gauge above a vessel of clean brine. On the object being heated by a blow-pipe flame, directed from above, when the correct temperature is reached it will automatically slide off the gauge into the brine and be quenched. While particularly adaptable for small tools, it can be used to advantage for large ones.
CONTINUOUS VACUUM-FILTER MACHINE.

Written for the Mining and Scientific Press
By Bertram Hunt.

In an effort to produce an efficient continuous filtration device for use in cyaniding slime, I designed a vacuum-filter, which contains features that promise high efficiency. The machine may have a stationary filter-bed or one with a revolving filter-bed. In the first form, the filter-bed is an annular chamber, the top of which constitutes the filtering surface. The filter used is a form of sand-filter which I first applied over fifteen years ago, and have used most successfully in leaching gold-slime.

In making the filter-bed, slats of triangular section are placed side by side but not touching, a space of about one-quarter or three-eighths of an inch being left between the bases of the slats. Carefully screened gravel, as nearly uniform in size as possible and too large to pass through the openings between the bases of the slats, is then placed in the lower part of the bed. Above this finer gravel or coarse sand is spread in a layer about 1 in. deep to form a floor on which is spread clean sand of 8 to 12-mesh size, to a thickness of an inch or so above the tops of the triangular slats. This forms the permanent filter-bed and is supported strongly enough to remain perfectly rigid on the application of a vacuum in the chamber underneath. This chamber is connected with a wet-vacuum pump or other machine which withdraws the solution and maintains the vacuum.

The walls of the structure may be made of concrete, and these being raised a couple of inches above the top of the filter-bed constitute circular tracks on which a carriage revolves. This carriage has an iron scraper in front, which is of the same width as the filter-bed, and removes the layer of residue from the permanent filter-bed. The residue is removed from the scraper by a screw conveyor, or by sluicing when water is available for that purpose, and is carried to the hollow central pillar of the machine from which it is carried outside by a conveyor or by water.

Following close behind the scraper, on the carriage, is placed a distributor similar to that used on a Frue vanner, which distributes the sandy portion of the pulp. Behind this is a second distributor which spreads the slimy portion of the pulp over the layer of sand just laid down by the first distributor. On the central column of the machine are two concentric hoppers or funnels, which are connected by pipes with the two distributors, and which receive the pulp. Before reaching the filter-machine the pulp is roughly classified, so that a portion of the sand is separated in a clean condition, and this clean sand is fed upon the filter-bed by the first distributor, the rest of the pulp going to the second. In this way the slimy portion of the pulp is always distributed over a layer of clean fine sand. As the carriage moves continuously the deposited layer of sand and slime is also continuously removed by the scraper, while fresh material is deposited by the distributors, as described above. Pipes to spray wash-solution or wash-water follow the carriage at suitable distances, so that the residue can be thoroughly washed.

When it is desirable to keep the strong solutions separate from the weak, the vacuum-chamber underneath the filter-bed is divided by partitions into a number of sections, the outlet from each section being equipped with suitably connected valves. These valves would be operated automatically so as to discharge the strong solution separately from the weak. Such an arrangement is an added complication, and in the majority of cases proves to be unnecessary. In the case of a plant in which leaching is done by percolation in vats it is easy and usually desirable to keep the strong and weak solutions apart, but a modern plant practising fine grinding and agitation, followed by mechanical filtration, the conditions are quite different. A machine which has to run continuously should be as simple and as nearly valveless as possible. In those instances in which it is desirable to keep the strong solution separate, two filter machines should be worked tandem, the strong solution being withdrawn from the first, and the washings from the second.

The machine illustrated herewith has an extreme diameter of 15 ft., the annulus being 3 ft. wide. This gives a filter-surface of 113 sq. ft. On the supposition that the layer of residue contains 50% moisture and weighs 109 lb. per cubic foot, if it is 1/4-in. thick, it will amount to 2.26 cu. ft., and will weigh 246 lb., or 123 lb. dry. At a speed of one revolution of the carriage per minute this represents an output of 3.69 tons of dry material per hour, or over 80 tons per day. I have taken 50 tons per day as my estimate of the net capacity of this size of machine.

A great deal has been published recently regarding the troubles incidental to the use of canvas or filter-cloth in filter-presses and vacuum filter-machines. The cost of repairs and renewals is large, and there is a necessity for periodical soaking in hydrochloric acid to remove the incrustation of lime salts, and for the employment of a subsidiary filter to clarify the solutions. With a sand-filter properly arranged these troubles do not exist. A clear filtrate is always obtained, and no subsidiary filter is required. This means a considerable saving in itself, and the elimination of the acid-treatment means a further economy as compared with canvas filters. Whenever it is desirable to clean the permanent filter-bed, the scraper, which is adjustable, is lowered, and the carriage revolved so as to remove the layer of sand above the tops of the triangular slats. Clean sand is then spread over the surface to the proper depth, the scraper is adjusted, and the machine is at once ready for work again. Little appears to have been done in the use of sand for filtering in hydro-metallurgical work. Possibly the reason has been in the difficulty of preserving a thin layer of sand without disturbing or washing it away. The distribution of a thin layer of slimy material on the top of a layer of sand from a slowly moving carriage with the consequent minimum disturbance of the sand layer, forms an ideal condition for rapid filtration. A continuous machine has many advantages in operation.
The load on the machine is steady, and the attendance required is small. A filter-machine of the size illustrated will require less than one horse-power to drive it, and four horse-power to maintain the vacuum. When a continuous filter-machine has been regulated as to the amount of feed, the rate of revolution of the carriage, and the speed of the vacuum-pump, it is practically automatic in operation, and continuous removal of the residue and the deposition of fresh material makes the efficiency constant.

A novel battery cell, described in a paper read before the American Electro-Chemical Society, consists of electrodes of aluminum and magnesium in a solution of aluminum sulphate, to which some hydrogen peroxide is added. Aluminum behaves in a peculiar manner in contact with dissolved air, or oxygen, and becomes electro-negative to a similar aluminum electrode in water free from dissolved air. Magnesium does not show this effect; hence a cell with the two metals for electrodes has a comparatively large electromotive force developed when dissolved air or oxygen is introduced. The effect is considerably increased by adding hydrogen peroxide. Tests were applied to the water in which clean aluminum had stood for a few hours, and a measurable quantity of hydrogen peroxide was detected. This was developed from the action of the dissolved oxygen on the aluminum, probably according to the following reaction,

$$2\text{Al} + 6\text{H}_2\text{O} + 6\text{O}_2 = \text{Al}_2\text{(OH)}_6 + 3\text{H}_2\text{O}_2$$

The amount of yield of the peroxide was considerably increased in several ways. Without dissolved air no trace of peroxide was observed. The generation of the hydrogen peroxide explains the abnormally large electromotive force developed between two metals so close together in the electrochemical series.

Japan's coal production during 1907 amounted to 13,716,488 tons.
METALLURGICAL CONDITIONS AT COBALT, CANADA.

By F. N. Flinn.

*With the discovery of the Cobalt camp, there were presented to mining and metallurgical engineers several problems, which made even the most capable and experienced pause before passing an opinion. To this day many of these questions are unanswered to the satisfaction of those who are developing the camp. The mining engineers were asked: "Will these narrow veins go down, and will their silver content continue in depth?" The metallurgists were asked: "How can we get the most dollars from our ores?"*

The veins are found in the Keewatin, Lower Huronian, Post Middle Huronian, and more recent formations. Their pitch is nearly vertical. They open and close frequently, both vertically and horizontally. The Lower Huronian veins are the most constant, the Post Middle Huronian ranking a close second. The veins outcropping in the Keewatin cannot be referred to in a general way, but some of the best veins are found in this formation. It is generally conceded that veins which are constant in the other formations, are apt to pinch out when they enter the Keewatin.

The veins are narrow, all under 28 in., probably averaging 4 in. wide, and according to the Provincial geologists they contain the following minerals:

1. Native elements.—Native silver, native bismuth, graphite.

2. Arsenides.—Niccolite or arsenide of nickel (NiAs). Chloanthite or diarsenide of nickel (NiAs₂). Smallite or diarsenide of cobalt (CoAs₂).

3. Arsenates.—Erythrite or cobalt bloom, Co₃As₂O₁₀ + 8H₂O. Annabergite or nickel bloom, Ni₃As₂O₁₂ + 8H₂O.

4. Sulphides.—Argentite or silver sulphide, Ag₂S. Millerite or nickel sulphide, NiS.

5. Sulph-arsenides.—Mispickel or sulph-arsenide of iron, FeAsS. Cobaltite or sulph-arsenide of cobalt, CoAsS.

6. Antimonide.—Dyscrasite or silver antimonide, Ag₅Sb.

7. Sulph-antimonides.—Pyargyrite or dark red silver ore, Ag₅Sb₂S₄. Tetrahedrite or sulph-antimonide of copper, Cu₃Sb₂S₆.

Some of the veins have the ore concentrated in one seam, lying loosely between two perfect walls, the line of separation being distinctly marked, usually by a film of mud. Such veins can be stripped clean in mining, providing the width and grade justify stripping the gangue before taking down the ore. Another type of vein has the ore 'frozen' to one wall. A third type contains several 'strings' of ore entering and leaving the main vein, leaving gangue rock between them. With these two types, the walls are not always clearly defined, and it is usual to drive in the ore, that is, to cut behind the walls with the main drive, sufficient to take down the outside stringers. By keeping the drill-holes away from the ore and loading them with just the right amount of dynamite, this method can be followed without producing an undue amount of 'finest.' A fourth type may have irregular walls and consist mainly of calcite and native silver, with sheets and flakes of silver penetrating the wall-rock at all angles from the main vein. These veins produce a large quantity of 'coblings.' In this refuse material the flake silver is quite visible before crushing, but is so thin as to produce little or no 'metallies' after crushing, the gangue being very hard. Another similar type contains the bulk of the silver as argentite instead of native, or as a mixture of both. These veins are not so frequently encountered as the preceding, but produce a larger tonnage of mill-rock than any in the district.

The mixed vein matter is treated on one or more bumping tables. These are frequently 4 by 15 ft., hung by inclined bolts from overhead timbers, having a fall of 1 ft. in 15. The forward motion is about 4 in., imparted by a cam-shaft at varying speed. The floor of the table consists of two steel plates and one perforated plate. The material is fed from a bin at one end, and sprayed continuously with water from the mine pumps. The perforated plate has 9/16-in. holes, while the under screen has 5/16-in. holes. This gives the sorters washed rock 3/4 in. and larger, while the undersize 3/4 in. to 1/4 in. and water, along with the coarse waste from the end of the table, drop into their respective bins below. One table handles 50 tons per shift with six men, including car-men. By arranging separate dumps for all these materials they can be more readily marketed, or treated by different processes. The shipping ore is usually crushed to one inch and sewed in bags containing from 75 to 150 lb. The following statement, from a paper read by Dr. A. R. Ledoux at the Toronto meeting, 1907, gives the only accurate published information of the average assays of cobalt ores in carload lots:

"Silver, of course, in point of value, is the more important element. The highest percentage of cobalt found in any one shipment is 11.96%, the average being 5.99%. The highest assay for nickel in any carload is 12.49%, the average being 3.66%. The highest percentage of arsenic is 39.32, the average being 27.12." A complete analysis of two carloads, which is given herewith, reveals the exceeding complexity of the ores, the high metallic content, and the extraordinarily small amount of silica and alu-

Combined water, alkalies, and oxygen, by difference, 1.35

For the moment the main object in milling is to win more ore from the waste, cobbles, and screenings. The treatment of the wall-rock proper will be the second step. Mixed material difficult to 'cobs' will undoubtedly add considerably to the output, but on account of its physical 'make-up,' and the fact that the ores of the district occur in the massive form, the crushing will produce a considerable quantity of slime. Stamp crushing should not be considered in concentration. Roll crushing, with a large slime-treating capacity, may serve for the present, but ample provision should be made for storing the slime separately. If the concentration process is confined entirely to the recovery of the arsenides, the extraction, plus the recovery of slime as such, should be quite satisfactory. On the other hand, should concentration be attempted on the wall-rock ores carrying native silver in very thin flakes and as argentite, the results cannot possibly prove a financial success, unless the tailing is to be re-treated by another process. The native silver flakes and argentite ores must be treated chemically if milled, preferably by amalgamation for the native silver, and by cyanide for the argentite ores, whereas the slime from concentration might be treated by the 'oil process.' At present there are six new concentrators in the camp, three in operation and three nearly completed. One plant is designed to treat the tailing by cyanide; the other by amalgamation.

The bulk of shipments from the camp have gone to the custom smelters of New Jersey, and as the ore is exceptionally rich, and special facilities are required in the sampling, it is almost invariably sampled at the public sampling works. Shovel sampling is preferred to mechanical samplers. Here in the presence of representatives from buyer and seller, the sags are weighed in lots of ten, by a public 'sworn weigher.' The ore is crushed, rolled, and re-rolled, the nuggets of silver being picked out by hand between each handling. The nuggets are weighed and deductions made. These are usually sold to the custom refiners as a separate transaction. The finely-crushed and thoroughly-mixed material is now completely sampled four successive times. The smaller samples are screened, and the 'metallies' are subjected to a further grinding in small pebble mills. The four samples vary widely in their values, in spite of all precautions. Cobalt and nickel are not paid for by the custom smelters in the United States. The ore carries no gold. Silver is the only determination necessary in most cases. This is determined by wet and dry methods on all ores carrying arsenic in quantity. The nuggets are melted in large crucibles and cast into bars. The resulting slag and speiss are weighed, sampled, and assayed as usual. The bars run from 700 to 875 fine.

The sampling of a mine dump by grab-sampling is not worth the cost; the metals are not homogeneously contained in the rock. The 'fine stuff' is invariably the richer. The silver in the coarse rock is in the crevices; whereas the body of the rock, without cleavage planes, is barren, so that, in shipping pieces from the larger rocks, one invariably gets a greater proportion of silver than the whole rock contains. To determine the value of the dump, a large quantity should be crushed and finely ground before sampling.

Let us assume that concentration, followed by a chemical process in special cases, will solve all the low-grade ore problems. This means a larger output of arsenical ores to be smelted. In the earlier days of the camp a considerable tonnage of arsenical ore was shipped to Europe, where, in some cases, the four metals—silver, cobalt, nickel, and arsenic—were paid for at very satisfactory prices. For various reasons, many of which are inexplicable at this end, the European metallurgists either declined to take any more shipments, or declined to pay for all four metals. Others later on declined to pay for nickel and arsenic, and at last only paid for the cobalt. The result is that those producing smatite ores without silver occasionally market a carload in Europe. The silver mines have practically discontinued European shipments. The New York ore buyers paid for the arsenic, silver, cobalt, and nickel as late as August 1905, when they discontinued payments for the arsenic, cobalt, and nickel. The new schedule, given out at that time, by the New Jersey smelters, charged 6% of the silver, and later they imposed a treatment charge of $8 per ton. As the European market declined, the treatment charge was raised to $9 and then to $15 per ton, with a silver deduction of 7%. Then followed the penalty for insoluble silica and arsenic. Later one-half cent per ounce was deducted from the price paid for the silver, and various other deductions followed, until a condition was reached where one smelter, unless the
mine owners would make a time contract at increased treatment charges, declined to accept any more ore. Strange to say, the other smelters, including the European plants, were at this critical time 'overstocked' with cobalt ores. After the mines had accepted the inevitable, the smelters broadened their field of operation, and allowed shipments to be made without restriction as to tonnage especially for wall-rock ores, which contained little or no arsenic. The new schedules still impose a heavy arsenic penalty on ores under 1500 oz. In December 1905 a carload of ore was shipped from Cobalt to England direct. The liquidation shows:

Weight—17 tons, 16 cwt., 3 qr., 3 lb.  
Contents—Ag 30,921.24 fine oz.  
Co 4,275 lb.  
Ni 2,496 lb.  
As 13,679 lb.

Total debits .................................. £159 1 7  
Net credits .................................. £4255 18 3  

The schedule offered by the American Smelting & Refining Co., Maurer, N. J., 1908, is: For ores under 1500 oz., pay for silver 93% of contents at New York quotation, less 1/2c. per oz., at quotation 30 days after agreement on assays. Charge for insoluble silica, 7c. per unit; for arsenic in excess of 5%, 25c. per unit; for treatment, 80c per ton. For ores over 1500 oz.; these are not purchased outright. They are cupelled in the refinery and paid for as follows: Pay for bar silver recovered from cupellation at New York quotation, less 1c. per oz., for 100% on date of agreement on assays. Pay for the silver contained in the by-products from cupellation at New York quotation, less 1/2c. per oz., for 98% of contents, at quotation 30 days after agreement of assays. Charge for treatment, $125 per ton of ore.

The schedule of the International Nickel Co., Copper Cliff, Ontario, 1908, is:  
Ag pay 94%, when 4000 oz. or over.  
" 93% " 1200 "  
" 92% " 800 "  
" 90% " 500 "  
" 85% " 300 "  
" 80% " 150 "  
Co pay $30 per ton of ore for 15% or over.  
" 320 " 8%  
" 110 " 6%  

No payment is made for less than 5% cobalt, nor when the nickel content is higher than that of cobalt. Payment is made in two installments at 45 and 90 days respectively, after sampling the ore, and is based on the official value at New York on the first day of settlement. The purchaser reserves the right to pay in silver bullion delivered at New York in place of cash.

The Swansea smelters in 1907 bought low-silver cobalt ores, without regard for silver contents, and without any deduction, f.o.b. cars at Cobalt, as follows:  
5% to 10% cobalt .................................. 30c. per lb.  
10% to 12% " 35c. "  
12% to 14% " 40c. "  
14% to 16% " 45c. "  
16 or over " 55c. "

These prices give net returns of from $45 to $160 per ton. The Swansea smelters raised their schedule of payment in 1908 five cents per pound.

Very recently German buyers have entered the field, and have purchased certain classes of ores at figures which are satisfactory to the Cobalt producers. They have bought several carloads of ore on the following basis: For ores containing not less than 10.5% of cobalt, and not less than 30 oz. silver per ton, there will be paid $81.82 per ton, on the following conditions, f.o.b. cars, Cobalt: Purchaser pays freight. Sampling by Ledonx & Co., Bergen Junction, N. J. The cost of sampling to be divided. Ledonx & Co.'s assays will govern settlement.

This would net say $80 per ton.

The most serious difficulty at the present time is the uncertainty of the cobalt market. The European buyers occasionally cable instructions to "ship 50 tons cobalt within one week," whereas the miner is not prepared to deliver in so short a time. It is not mined until a market is found for it. Should he ship, he might wait six months before receiving another offer.

It seems scarcely necessary to add that the market price of silver today would materially change these results, and that contracts for time or tonnage on the entire output of all classes of ores produced would result in slightly better terms.

In the lead cupellation process the advantage is that many difficulties and uncertain results in sampling and assaying the rich crude ores are eliminated. The disadvantage is that the losses resulting from handling, fine dust, and volatilization fall on the seller. Roughly, about 60% of the silver is recovered in bars. The advantage of eliminating an uncertainty in sampling and assaying is as beneficial to the smelter as to the seller. On the other hand, the metallurgical losses are always borne by the seller. This loss, in addition to a treatment charge of $125 per ton, and deductions from the percentage of silver paid for in by-products, as well as from the market price paid for the silver in both instances, and together with the fact that the seller is not paid for his cobalt, nickel, and arsenic by the New Jersey smelters, appears to the average miner as a condition wherein the term 'modern metallurgy' is a delusion.

**Mining costs** by contract in the State of Jalisco, Mexico, as shown in a recent report by the El Favor Mining Co., averaged as follows for the year 1907: Driving 1463 ft., $6 per ft.; sinking 318 ft., $9.75; raising 209 ft., $5.25; and cross-cutting 336 ft., $3.87 per foot.
MINING AND METALLURGICAL PATENTS.

Specially reported for the Mining and Scientific Press.

In a drill sharpener, a supporting bed, a vise for holding the drill, a cylinder secured to the bed, a cylindrical shell reciprocably mounted in said cylinder, a hammer reciprocably mounted in said shell, a die-bar supported by the shell in axial alignment with said vise and drill, and arranged to project into the path of the hammer, an additional die support fixed on the bed, means for actuating the hammer, and means for moving and holding the die-bar against the end of the drill during the stroke of the hammer against it.

A classifying apparatus having in combination a separating chamber in which the operation is carried on, a feed-pipe leading to said chamber to convey the material to be treated under continuous pressure, said apparatus having a supplemental classifying chamber below the separating chamber, a screen dividing said chambers, said apparatus having a hydraulic sizing chamber connected with said feed-pipe, and said sizing chamber having a discharge conduit leading therefrom and discharging tangentially into said supplemental chamber, whereby there is produced a rotating motion of the contents of said chamber.

In combination, a sluice or box having transverse amalgamating pockets adapted to contain mercury, and draw-off outlets in said pockets, with a removable cover adapted to cover any pocket to permit the latter to be emptied, said cover having an opening in it to permit access to the pocket covered thereby, substantially as described.

A filter-frame comprising a frame, a filter-plate within the frame having transverse and longitudinal interconnecting grooves on its outer surface, a filtering medium surrounding the filter-plate, and means for detachably securing the filtering medium to the top and ends of the frame.

In an ore-pulverizer the combination with oppositely disposed screen heads and a die ring detachably mounted and clamped between the heads, one of said heads having a central opening; of a tubular device projecting through the opening and bearing against the opposite head, said device having an outlet opening, driving means connected to one of the heads, a pivoted support for the feed device, and a plurality of connected crushing rolls movable around the feed device and upon the die ring, said rolls being disposed to travel longitudinally of the outlet in the feed device.

In a mine apparatus, the combination with a car track and a hoisting cage, of car restraining means carried by said cage and comprising a rock shaft having a dog at its forward end adapted to control a car while upon said cage, and a crank arm at its rear end, and means associated with said car track adapted to be engaged by cars while moving on said track and engaging the crank arm so as to actuate said car-restraining means, substantially as set forth.
Coal-Carrying Aerial Tramway.

In the fierce race for supremacy which obtains in the operation of mines, to increase the output at the least possible expense, the aerial wire-ropework tramway has played an important part. Today competition is so severe that, to survive, operators must equip their mines with every modern appliance. Electric half-way measures or inferior apparatus for mining and transporting minerals may be tolerated if the tremendous pace is to be maintained. Years ago pack-mules were pressed into service for the transportation of minerals; but mule-power has nearly seen its day, and the substitution of aerial wire-ropework haulage is an absolute necessity. Transportation by means of aerial wire-ropework tramway is a system perfectly simple in mechanism, inexpensive in reduction, produces 20 to 30 per cent. lower costs of transportation than to a minimum, and it is easily handled, both in installation and maintenance. It is absolutely reliable in action under any and all conditions. It is adapted to the transportation of coal, ore, sand, rock, and lumber, over any contour, and for any length of line from 100 ft. to twenty miles or more.

The economy of wire-ropework transformation is fully demonstrated at the mines of the Montana Coal & Coke Co., of Butte, Montana. Their property is situated, is nestled picturesquely in a beautiful valley at the foot of Electric Mtn. The valley is 5185 ft. above sea-level. Towering mountains, with peaks clad with snow ten months of the year, surround the valley on every side. So circuitous is the road leading to Electric that, having reached the town, it is difficult to determine the presence of the wall of peaks. A valley of this character would seem to form a complete barrier to the outside world. This town is situated on the Gardner branch of the Northern Pacific railroad, about four miles from the famous Yellowstone Park. Twenty-eight years ago J. Beattie and J. W. Roese opened a coal claim here of 320 acres. This was later taken up by the Herr brothers. The Park Coal & Coke Co., with Horace F. Brown as president, succeeded the Herr brothers, and began to ship coal, and coke was made with a battery of five ovens. Twelve years ago the property again changed hands, coming into the possession of the Montana Coal & Coke Co., the present operators. The property of this Company now aggregates approximately 1400 acres. There are now 285 coke ovens of the bee-hive type, each having an individual capacity of 6 to 7 tons of coke per day. Both 72-hr. and 48-hr. coke is produced, all of which is shipped to Butte, Mont., to the Anaconda Copper Mining Co., the Butte Reduction Works, and the Pittsburg Montana smelter. Before being cooled the coal is ground fine and, washed in a Lahring washer.

The coal is in the mountains, and these seams constitute the most disturbed field now being worked in this country. Some veins were thrown 1000 ft. perpendicularly when the mountains were formed. Operating under the conditions prevailing in this mountainous region was both difficult and expensive, because of the extremely crude method of transportation between the mines and the shipping point.

The coal was transferred to the valley below by a relay of large wooden shovels. It reached its destination so badly broken that little of it was fit for domestic use. Early in 1907, Edmund A. Bartil, general manager for the company, was detailed to inspect the property and recommend such improvements as he thought would reduce the cost of production to a reasonable figure. His opinion was that an aerial wire-ropework tramway was the only method of transportation that would work. Contracts were soon let for three Gummer tramways, 4100, 7200, and 7500 ft. long, respectively. Ground was broken immediately for the towers, and within 60 days all material for the three tramways was on the way, consisting of 10 car-
loads of machinery and wire rope. Great difficulty was en-
countered in hauling the material from the railroad to the
valley to the places along the line of the tramway in the
vicinity where it was to be used. So rough and steep was
the road that at times it was necessary to supplement the
eight-horse team with rope and windlass.

The 4100-ft. aerial tramway is operated wholly by gravity.
Two descending loaded buckets keep it in motion and hold
all the empties. Last summer, when the mountain spring
from which the mining camp derives its water supply
had become exhausted, water from the valley was sent up in
the tramway buckets. The speed of the line is approximately
300 ft. per minute, and is controlled by three brake-wheels,
attached to the main terminal shaft at the loading station,
and slipped with brake-bands lined with hard-nail bolts.
The loading station is on the Elkridge & Bascom's yellow
straw 'Powersteel,' 1 in. and 1 1/2 in. in diameter. The loading
strains of these cables are 48 and 72 tons, respectively.
The traction-rope is the Broderick & Bascom patent steel cable,
which is superior to the ordinary crucible cast-steel rope.
Tension on all ropes is maintained by automatic weight-
boxes. Swivels attached to the ropes permit of their being
traversed, so as to evenly distribute the wear. All the stations
on the line are connected with each other by the rest of
the plant by telephone. To go by wagon from the loading
station to the discharging station takes about one hour,
while the buckets travel the entire 4100 ft. in 10 minutes.

Buckets are loaded, transported 4100 ft., dumped, righted,
locked, and returned, without power and with little atten-
tion. At the mines of the Montana Coal & Coke Co., the
coal is hoisted by electric power and dropped into the bunks
of the tramway loading-station. From these bunks it is
drawn into the buckets by an ingenious device known as the
Gemmer patent automatic loader. This loader consists of a
two-compartment hopper, mounted on trucks, traveling on
independent rails. An attendant fills this loader by opening
the gates of the coal-bunker. A bucket, on entering the load-
ing-station, drops a supplementary track-rope onto a
steel rail, but is not detached from the main-cable. The
cable passes around the automatic grip-wheel having 106
pairs of grips in its periphery, which open and close upon
the rope automatically, preventing it from slipping. After
the bucket passes around the automatic grip wheel it en-
gages a pair of actuating levers which are attached to the
automatic grip-wheel. As to every reason of this connection the
loader is gradually accelerated to the speed of the incoming
bucket, at which time the gates on the loader open automatically
permitting the material to flow into the bucket from both
sides, loading the bucket evenly. The bucket and loader,
during this operation, travel together a distance of approxi-
mately 12 ft., while the loader is automatically disconnected
from the main cable, the gates close automatically, and the
loader recedes automatically to its normal position, where
it is re-charged, while the bucket passes out over the line
to the discharging station. An additional attendant is sta-
tioned here to operate the levers which control the speed of
the line. One attendant could manage the loading of the
buckets and control the speed of the tramway, but it is con-
idious to employ two because of the steep incline.

Midway between the leading-station and a prospect open-
ing. By locking the automatic loader at the main loading-
terminal, one or more buckets can be passed through un-
loaded. Thus, by a pre-arranged plan, every other bucket,
or every third or fourth, can be left empty at the main
loading-station, to be loaded at the intermediate station,
or vice versa.

On the arrival of the buckets at the discharging station
an automatic trip releases the tripping handle, allowing
the bucket to discharge its contents into a bunker. This opera-
tion takes place while the bucket is in motion. It then
rights and locks itself and returns to the loading station.

Only three attendants are required to operate this entire
4100-ft. tramway. Two of these are at the main loading
station and the other at the intermediate stage. Placing
their wages at $2.50 per day each, and the daily hauling
of the tramway at 200 tons, the cost per ton is 25c. In
the event that the tramway were driven by an electric
motor, one man would be sufficient to operate the tramway,
as one attendant would be capable of not only handling the
levers controlling the flow of the material from the ore-bin
into the automatic loader, but he could also control the
switch on the motor regulating the power.

There are 11 towers on the line of the tramway, the legs
of which are made of round timber cut from the adjoining
woods. The towers of sawn timber were made at a mill on
the ground. The two tallest towers are 45 and 72 ft., respec-
tively, the latter being constructed in a similar manner to
the towers used in the oil fields, built of 2 by 12 in. timbers,
the legs forming an angle. The result is a rigid tower at
moderate cost. The longest span between towers is approxi-
mately 600 ft. The iron saddles for the track-cable, and the
buckets supporting the traction-cable sheave on the tow-
ners were cast together, thereby forming a unit at all times
the proper distance between these two cables. All sheaves
on the towers and at the intermediate station are of steel,
fitting with phosphor bronze bushings.

The Gemmer tramway bucket is absolutely self-operating.
The buckets on some systems require an attendant to right
and lock them. Others use complicated machinery to do
this work. With the Gemmer bucket, however, that gets
swings outside the rail, resulting in a derailment of the
carriage. This bucket is made of heavy sheet-steel, rein-
forced with steel-angles in the corners. The traction rope
is attached to the bucket a few inches above the track-cable
instead of considerably below it, as in some types of tram-
way. In these types there is always a tendency for the
rope or cable to be caught by the bucket when the car starts
or comes to a stop, causing a reduction in service.

This particular true when ascending or descending a
grade, as when nearing a tower or in places where the topo-
ography is steep.

There are 29 buckets, each having a capacity of 1400 lb.
of coal, or 25 cu. ft., spaced at intervals of 410 ft. This
gives the tramway a capacity of 30 tons per hour, or 300
tons per 16hr. day. Twenty buckets are turned at any time,
doubling the capacity, and this will not increase the
cost of operation, as the same number of attendants
can handle the tramway. The buckets are attached perma-
nently to the traction-cable by means of Brown tramway
clips, which ride over the sheaves perfectly, with no tend-
ency to derailment. The connecting pin on the clip is held
by a device on the bucket in such a manner that it gets
as a swivel. No matter what the gradient, there is no tend-
ency to pull the bucket from its perpendicular position.
This is of particular advantage on this tramway, where
the gradient is approximately 45° in several places.

The plant of the Montana Coal & Coke Co., which employs
400 men, is now one of the most up-to-date in the country.
The plant is one of the most prominent in the west.

According to Government statistics, 1,829,921 short tons,
of a spot value of $3,240,367, was mined in 1906. This is an
increase of 156,089 short tons over 1905, or 11.3 per cent.

Publications Received.

The Official Mining Directory of Mexico. Published
under the authorization of the Government, Vol. X. Qto.,
pp. 244. Ill. By John R. Southworth and Percy G. Holmes,
Mexico City, Mex., 1908. Price $5, U. S. C. For sale by
the Mining and Scientific Press.

The official character of this directory is, of course, only
a matter of courtesy, but the publication is well known
and has made its own reputation as a valuable guide-book.
As each works goes up in the country the name of the
company or individual company becomes known. The type
is large, clear, and open, the maps are abundant
and helpful, and the work is sprinkled from cover to cover
with handsome half-tones which reveal the leading mines
and smelters of the Republic. A short sketch of the
history of Mexican mining is given, a re-print of the
mining laws, various statistical tables, weights, and measures,
a directory of mining officials, a list of the important
types of mining companies is classified first as to States,
arranged in alphabetical order, and under each State the
companies in similar order. The information given under each head-

September 26, 1908.
Richards Pulsator Classifier.

The Richards pulsator classifier is the invention of Robert H. Richards, the renowned author of the recent book on ‘Ore Dressing.’ Hydraulic classification of ores has received Dr. Richards’ special attention for many years, and the pulsator classifier is the crowning result of an evolution in the form and application of hydraulic classifiers. By its use, it is stated that concentrating tables are increased in capacity and in the cost of handling the ore, which has been increased from 2,000 a. to 9,000 a. or more, with a corresponding increase in recovery of valuable minerals. It is not intended here to discuss the effect of this new apparatus on the general problems of mining; the object of this paper is to present the facts as to its mechanical construction and operation. It is a remarkable invention, and one that is certain to bring about a great change in the mining industry.

The choice between the use of screens producing a steed feed and the use of pulsator classifiers is a question of postulating the tables, is a much mooted question, each method having different advantages. The choice has been influenced principally by the performance of the machines, rather than by a difference between the recovery, treating either perfectly sized or perfectly classified material.

The objections to screen-sizing finely crushed pulp are mechanical. The standard form of revolving screen, used with fine screen-cloth is a clogged source of trouble. The efficiency of such a screen is low, requiring for any considerable tonnage a screen of vast proportions. The screen cloth ‘blinds,’ that is, the openings clog, requiring almost constant attention. Numerous attempts have been made to overcome this trouble with shaking or bumping screens. In all of these the object is first to distribute the ore entirely over the screen-cloth employed, and second to keep the screen-cloth from clogging. It is difficult to keep the shaking or bumping type of screen in repair, as all successful concentrating mills operate 24 hours per day, and the difficulty of keeping a machine which is shaking or bumping at the rate of from 200 to 400 strokes per minute in repair under such conditions can readily be appreciated.

The Richards pulsator classifier is a simple mechanical device, requiring little attention. It is a remarkable machine in its capacity as compared with its size, when considered in comparison with previous forms of classifiers, and in the quality of work it performs, that is, in the perfect classifier which it effects. The machine shown in the accompanying illustration is a standard 6-in. six-compartment Richards pulsator classifier. It has a total capacity of from 150 to 200 tons of ore in a properly thickened pulp per 24 hrs., which it delivers in six different classes. Standard spitzkasten are seldom used for more than four classes of product. One spitzkasten handling 150 tons of thickened pulp would be of prohibitive size, and in practice two machines, each handling 75 tons per 24 hrs., would be installed. Assuming that these two spitzkasten are set side by side, the comparison between the Richards pulsator classifier and the spitzkasten is as follows:

In the above figures the height of the air column on the Richards pulsator classifier is not included, since the portion of the machine occupies space which would otherwise be unused. The classifying current maintains a constant agitation of the ore from the moment the ore enters the machine until it is discharged as a classified product, hence groups of particles are broken up, insuring that each class of material will be delivered from the proper spigot. In both the inverted and the direct forms the lighter finer particles are liberated from the heavier particles by the agitation, and in the inverted form the velocity of the classifying current in the first compartments is sufficient to lift the heavier particles, while in the direct form the velocity of the classifying current in the first compartment is so great that the finer particles cannot settle against it. This thorough agitation of the ore from the moment it enters the machine until it is discharged washes the free, fine, mineral particles off the large gangue particles to which they are clinging when fed to the machine, and discharges these small mineral particles with the fine product to which they belong.

The increased ratio of equal settling grains effected by the Richards pulsator is also of great value in the economical treatment of finely crushed ores. When the ore is crushed so fine that the condition of an absolute liberation of mineral from gangue is approached, then a close relationship between the size of the grain and its mineral content is established, and a fine screen can be used as a rough concentrator. Treating copper ore wherein included grains are still found after the ore is finer than 150-mesh, the Richards pulsator classifier is fed with ore ranging from 2.5 mm. (5-mesh No. 13 wire, approximately) to zero, and the tables treating the fine product themselves produce middlings and tailings still high enough in copper to make further recovery advisable. This middling and tailing are screened over a screen of very fine mesh, and the oversize is sent to waste, while only the undersize is further treated.

It is no exaggeration to say that this apparatus constitutes the most radical, important, and valuable improvement in ore-dressing appliances that have been placed on the market for many years. The Richards pulsator classifier is the first machine that will actually classify, separating the slime from coarse, in such perfection that the water discharged with the coarse material from the classifier is as clear as drinking water. The Richards classifier is also remarkable for the small space required, and for the amount of work done, as compared with the most perfect forms of classifier heretofore known. A spitzkasten to handle 150 tons in 24 hours, would require two machines 40 ft. long by 9 ft. high by 25 ft. wide, whereas the Richards pulsator classifier, doing the same work, occupies a space only 6 ft. long by 3½ ft. high by 2-3 ft. wide. This machine is built by the Delaval Engineering Works Co., and has been adopted, among others, by the Beaver & Montana Co., Copper & Silver Mining Co., Great Falls, Mont.; the St. Joseph Lead Co., Flat River, Mo.; Tombsby Gold Mines Co., Ltd., Telluride, Colo.; Colusa-Parrot Mining & Smelting Co., Butte, Mont.; Federal Mining & Smelting Co., Wallace, Idaho; and Nacozari Copper Co., Nacozari, Mexico.

zation, a factor in promoting international goodwill, and a stimulant to business between regions far apart.

OME, and the Seward Peninsula in general, has suffered this year from lack of water, so that the output of gold during the season now coming to a close will be much less than last year. It is likely to be from $4,250,000 to $4,500,000, as compared to $7,000,000 last year, although it is well to add that the official estimate for 1907 is considered to have been a little too high. There was no rain this year until July 31, and the meteorological record confirms the statements of the observant inhabitants: thus, during the first half of 1907 the total precipitation was 10 inches, while during the equivalent six months in 1908 it was only 3.49 inches. The water derived from snow lasted to the end of the first week in June, and by the end of July many of the placer mines were compelled to cease operations. Even in the high lands, at 700 to 1000 ft. above sea-level, where the ditches have their intake, there was but little snow this spring, so that the miner became dependent on ground-water and upon rain, the one an inadequate and the other an uncertain source of supply. Nevertheless, the outlook for the Seward Peninsula is cheerful, for evidence is accumulating that there are large areas likely to become profitably productive when exploited by methods consuming less water, and they are likely to be the sources of much gold during normal seasons when a moderate quantity of water is available. Nome and its tributary districts are not worked out, nor will they be exhausted for many years to come.

IT WILL BE NOTED that our correspondent at Johannesburg records the fact that the Minister of Mines has arranged for the assay and analysis of minerals for prospectors at moderate fees. In the States of Australasia similar aid to mining exploration is rather the rule than the exception. In the Yukon the Federal Government of Canada employs an assayer, stationed at White Horse, whose duty it is to make assays gratuitously, and we were informed by him that he was frequently in receipt of samples coming from American territory and sent by persons desiring to avoid payment of fees. While opposed to such paternal government aid as may stifle initiative or compete unfairly with the practice of professional men, we are constrained to admit that in new countries there is good reason for the establishment of Government assay-offices. In California and Nevada, for instance, we need no such help, but in a sparsely populated region where there is not enough assay business to justify low charges for testing samples, it is conceivable that many discoveries of mineral are either not made at all or postponed for lack of proper investigation. In Alaska, for example, there occur deposits of many minerals unfamiliar to the average gold prospector, not to mention the quartz veins that are tested by the pan only. It is not realized by the placer miner that there are many deposits containing gold that yield but scant evidence of richness by mere washing of a grab sample, and this fact is today hindering the exploration of the North. Insufficient sampling and assaying have retarded the development of many mines and many mining regions.

Drills and Drill-Steel.

IN OUR ISSUE of September 19 we published a valuable contribution on drill-steel by Mr. Eugene P. Kennedy, the assistant-superintendent of the Alaska-Treadwell mine. Such transcripts from actual experience are always appreciated by the readers of this journal, no less than they are welcomed by the editors. A recent visit to the great mine on Douglas island prompts us to refer to the use of cruciform steel, with a view to emphasizing the value of Mr. Kennedy's observations. It was an experiment with the Waugh drill, which uses all kinds of chuck-bushings, that suggested the idea of using cruciform steel in the standard piston-drill. The operator of the Waugh drill used 1½-inch steel in a square chuck, or 1½ and 1-inch steel in a cruciform chuck. He claimed that the steel provided was too heavy for his machine and, in order to make the test satisfactory, it was arranged to insert 1-inch steel into a cruciform chuck. This incident will amuse those who know how difficult it is to make reliable drill-tests; usually there are prejudices on both sides: the foreman of the mine is likely to be opposed to any change, and the agent of the new machine is apt to ask for ideal conditions, such as will spoil the experiment.

In the Alaska-Treadwell mine it has been the custom to employ Ingersoll-Sergeant drills of 3½ and 3¾ in. (for sinking) piston-diameter. From time to time other drills have been tried; thus, the smaller 2½-in. piston-drill of the same make has been employed for cutting-out stopes and drifts, and it is undoubtedly an economical machine when properly used. The trouble is that the men fight the introduction of the smaller stope-drill, for it means harder work. In running the larger machine, two men are required to set the drill in place, and once the drill is started there is not much to do but crank the machine; in consequence, any difficulty that arises is shared by the two men. With the machine that needs the service of one man only, the single operator has to erect the drill, start the hole, throw in water, change the steel, and keep his machine in alignment, all by himself. Therefore it is not unusual for the men to hammer the drill, break the bolts, and generally give the objectionable machine as poor a chance as possible, in the hope of proving it less serviceable than the two-man drill. On the other hand, in a mine that is well managed the chuck-tender on the big drill can be kept busy in fetching steel when the machine is running, while with the one-man drill work stops entirely when the driller absents himself. It becomes desirable to have a gang of 'nippers', say, one for every five stope-drills. A car running on an inclined track in the man-way could be used for lowering steel, so that the helpers would have to go only 100 to 150 feet, at most. Even if two men do not seem required when all goes well, it is found in
practice that whenever the drill is ‘binding’ or running badly the two men are needed to adjust the machine, one moving it, while the other loosens or tightens the bolts.

The Treadwell experiment proved that the Waugh hammer-drill was well adapted for special purposes, although not strong enough for the work of the big stopes where the footage was only one-half that made by the larger piston-drill. At Goldfield, we saw the same drill in the Florence mine under conditions much more favorable to competition with the piston-drill. Each has its scope. For making holes for plugs intended to hold electric lights, for survey and roller holes, for pillar plugs, and the like, the Waugh will prove useful even in the Alaska-Treadwell mine. For breaking chunks of ore in a choked chute, the Waugh is serviceable: but ordinarily the delay in getting an air-pipe connection renders ‘bulldozing’ (the placing of dynamite on the rock without drilling any hole) more expeditions. In matters of this kind academic instructions are useless. The intelligent observation of the foreman must supplement the technical training of the superintendent. Thus, the use of cruciform steel came by orderly development. Originally, the chuck-bushings were round and the octagonal steel had to be rounded to fit; then the bushing was changed to an octagonal shape, avoiding the rounding of the shank of the drill. Later, a cruciform bit was used, and at first 14 inches of cruciform steel was welded onto an octagonal shank such as would fit the chuck-bushing. To avoid the expense of welding and to make a better tool (for the swell at the weld is bad in dry holes), it became desirable to employ drill-steel and chuck-bushing both of which were cruciform. Two machines were tried for five months before the alteration was made general throughout the mine, as related by Mr. Kennedy in his valuable article. We shall be glad to hear from other superintendents in regard to this subject.

Politics and Business.

A MINING ENGINEER resident at Tokio writes asking us how the coming election will influence business in the United States. Another reader at Melbourne wants to know if the reform movement in America is making any progress. Both of our enquirers take it for granted, as they are fully warranted, that this journal is not involved in political controversy, and is therefore able to describe the situation without prejudice. Surely it is a most interesting period in American history. The assassin who ended the life of William McKinley was the unwitting instrument whereby Theodore Roosevelt was promoted to the presidency, after his enemies had supposed him safely shelved in the decorative office of vice-president. McKinley’s second term had barely begun, so Mr. Roosevelt served for nearly four years before he went to the people for election to succeed himself. In that campaign of 1904 he did not run against Mr. Bryan, but against a man so little known as to prove a weak competitor. His triumph was complete. By his fearless insistence on a high standard of public duty, by his extraordinary energy, by a mingling of impulsive frankness and clever policy, by a breezy manner and a cheerful optimism, his evident honesty of purpose, he caught the fancy of the people, for in him were personified the qualities that are distinctively American. During the last four years he has become the effective spokesman for the party of reform, incurring thereby the resentment of many of the leaders in his own party and arousing the animosity of the group of rapacious financiers into whose hands the control of business and politics was surely drifting. Having given his word not to try for re-election in 1908, he made it his affair to see that his successor should continue his policy, and to that end he chose William H. Taft, an able administrator, who had been Federal judge, Governor of the Philippine Islands, Secretary of War, and in these and other offices had proved himself to possess both unusual capacity as an executive and a high ideal of conduct. When the Republican convention met to select a candidate there never was any doubt as to the outcome. For Mr. Roosevelt’s leadership was unquestioned, and his recommendation of Mr. Taft proved more than enough to ensure nomination. It was said by the Democrats and others that the President dictated the doings of the Republican convention; it was a fact that he had so firm a hold on the imagination and affection of the rank and file of his party that there was every wish to select a man likely to follow in his footsteps. So much for that side. On the other stands William J. Bryan. Twelve years ago he won the nomination as candidate for President by reason of a florid oration that stampeded a Democratic convention. He was defeated by McKinley in 1896, and again in 1900. In 1904 his own party chose another standard-bearer. This year there was no doubt as to his nomination, for no other Democrat had equal claim to leadership and the convention that selected him was so enthusiastic in his support as to make the outcome certain. It speaks well for representative government that the two candidates before the American people at this time are such as would be chosen by a plebiscite. For Bryan is a logical candidate, no less than Taft. First a country lawyer, then a clever speaker, without experience of public service save as congressman for one term, then an editor, but continually before the public as an effective and persuasive orator, he has gradually gained experience as a politician and won the affection of a large portion of the people as a sincere reformer. His private life has been blameless; his public record has been clean. An unprejudiced judgment will allow that he is an honorable radical. One great function he has served: he has been the safety valve for popular unrest. In the days before Roosevelt led the party of reform, when the business interests identified with the tariff and the trusts were the pets of the Republican party, when such politicians as Platt and Depew, Aldrich and Grosvenor, were in the ascendant, Bryan was the spokesman for those to whom a corrupt plutocracy seemed a hateful outcome of this great experiment in representative government. So we dare to say to our friends in Tokio
and Melbourne that the United States is fortunate no less in Bryan than in Roosevelt. Save for them we should have had to choose between socialism and an oligarchy of industrial pirates. It is our deliberate opinion that if McKinley had lived out his second term, and had been succeeded by some other one of the group of men so closely allied to the great corporations that controlled the railroads and manufactures of this country, we should have seen a practical end to popular government in America. If the reform movement had not made headway, by reason, in part at least, of the oratory of Bryan and the virility of Roosevelt, we should have seen wealth accumulate so fast, by turning water into golden wine on Wall Street, that twenty men within ten years would have possessed $100,000,000 apiece, and would have used their financial power successfully to debauch the cheap legislators at Washington and at the various State capitals. Legitimate business has nothing to fear from the outcome of this election; Taft is a man of rare sanity and good humor; Bryan is no firebrand, he is as honest and patriotic as any man that ever lived in the White House. Taft plays golf; Bryan plays at farming. The American people is attending to business affairs, relaxing its attention only when something spectacular happens. Therein lies a danger. Attention to the duties of citizenship is confined largely to those to whom politics means business: the 'pocket nerve' responds more readily than the intelligent understanding. Movements of reform appeal to the dissatisfied and disgruntled, the number of whom varies directly as the sum of general prosperity; on the other hand, any effort to cure abuses meets with the organized opposition of those among the rich and powerful to whom reform means interference with facilities for making money rapidly. The United States needs more men willing to devote their time and money to the public service, to check the power of those to whom politics is either a species of blackmail or subsidized legislation. The young men of the country have been stimulated to a higher sense of patriotism by such fearless devotion to duty as that exhibited by the President, by the present Governor of New York, and, it is fair to add, by Mr. Bryan, who has spent his life in the advocacy of reform. At present the prosperity of the country, even after a panic, is inimical to violent reform; manufacturers are unwilling to see any tinkering with the tariff and will support the party in power; the realization that the tariff is the incubator of trusts will not influence many voters to take the opposite side. Whether Bryan or Taft be elected, the next Congress will be Republican, and there is no probability of any violent change in the protective policy of the United States. For the rest, the pre-occupation of the people and the revival of business activity following upon the presidential election, will tend to throw the brake upon the wheels of legislative change. In the meantime thoughtful men of other progressive countries may well give thanks; we have escaped the danger of having a reactionary in the President's chair, for a Cannon or a Fairbanks, a Foraker or a Bailey, would have given fierce vigor to the uncertain steps of socialism and would have checked severely the progress of representative government in every civilized country.

Wash Sales.

IN CONSEQUENCE of an investigation made by the Board of Governors of the New York Stock Exchange, the two members of a bankrupt brokerage firm were expelled because their conduct was held to be "inconsistent with just and equitable principles of trade." On August 22 they had recklessly committed themselves on the short side of the market for securities aggregating more than 558,000 shares, and on the same date, to take advantage of the demoralization expected to result from their raid, they had distributed orders for the purchase of securities totaling not less than 750,000 shares. At this time their entire available financial resources were insufficient to cover an advance of 1 per cent in the price of the securities of which they were short. They involved themselves toward their fellow-members of the Exchange in commitments vastly in excess of their ability. They failed in their game, and their failure injured many innocent persons. In defense they claimed that there was no rule establishing any proportion of capital necessary for members to transact business. The committee appointed to investigate was urged to make a public statement concerning the whole subject of fictitious trading. But the majority was opposed to the idea, the argument being that the time was inopportune and discussion of the question might lead to exploitation in the presidential election. It is high time that the Governors of the Exchange took action to stop 'wash sales', 'matched orders', and all the other methods by which spurious speculative activity is manufactured by adventurers. It is well known that the business of Wall Street is largely augmented by bogus dealings intended to inveigle the simple-minded that linger on the outskirts of that exciting hippodrome. In dull times it is necessary to go through the motions of buying and selling 500,000 shares in order to get one real purchaser of 100 shares. And it is not only the small brokers that play this confidence game. The big financiers manipulate the market with a freedom as great as their resources warrant, and find it easy to regulate the speculative barometer as they wish, except on occasions when unexpected events upset a shrewd program. Too much of the brain energy of the country is devoted to this betting on stocks, too many dynamic men give their lives to it, too much money is tied up in an unproductive industry. If the hundreds, even thousands, of clever men now playing with stocks were withdrawn from the Monte Carlo of Wall Street and were to devote abilities of a high order to productive industry—to farming, to mining, to constructive labor—the country would be enriched greatly. Not many would be needed to register the bona fide sale of securities. The community might then hope to be less obsessed by the spectacle of wealth accumulated by shillaney, and the life of the people would be less involved in the feverish anties of those that gamble.
Personal.

ROBERT M. RAYMOND is here.
W. H. SOMERSON is at Nome, Alaska.
F. L. Morris has returned from Idaho.
LEWIS T. WHITK has gone to New York.
ROSS E. BROWNE is in the Car of Aline.
ERNST DENICK has gone to Chihuahua, Mexico.
H. E. WEST is at Fredericton, New Brunswick, Canada.
J. H. CURLE has returned to London, from South America.
C. M. FUELLER, of Denver, is on his way to San Fran-
cisco.
W. S. NOYES has returned to San Francisco, from Ariz-
ona.
JAMES W. NELL has returned to Pasadena, from Salt
Lake.
EDMUND JUENSEN is expected here, on his way to Blair,
Nevada.
J. B. AARON is on his way from London to Western
Australia.
LIONEL LINDSAY has returned from a tour in Spain. He
is at Denver.
W. H. LANAGAN is with the Wild Goose Mining & Trading
Co., at Nome.
HENRY BRENTNER has returned to Tacoma from south-
eastern Alaska.
N. SAMWELL is testing dredging ground in the Salveon
district, in Burma.
W. B. BREITETZ is chemist at the Bakalaka smelter, in
Shasta county, California.
JAMES F. KEMP has returned to New York, from journeys
in Mexico and the Southwest.
FRANK M. WOON is superintendent of the Three Friends
dredge, near Solomon, Alaska.
ISIDORE TOM is with the Associated Gold Mines company,
at Kalgoorlie, Western Australia.
GELASIO CANTANI has returned from Europe. He will be
in San Francisco until October 10.
HENRY F. LEYVER passed through Butte, on his way to
the Georgetown district, in Montana.
GEORGE S. BINCLEY has returned to Los Angeles from a
professional journey to British Columbia.
R. D. HUNTER, manager of the Northern Light Mining
Co., has returned to Oakland, from Nome, Alaska.
GILBERT H. RUSSELL is superintendent of the Blue Goose
Dredging Co., on Ophir creek, near Council, Alaska.
T. LANE CARTER, manager of the French Rand mine, Jo-
hannesburg, is visiting the gold mines of the United States.
C. T. DUKE has left the Philippine Islands for Denver,
Colorado, by way of the Strait Settlements, India, and
Europe.
M. A. NEWMAN, manager of Cia. Minera Jesus Maria y
Anexas, of San Josè de Gracia, Sinaloa, Mexico, is in San
Francisco.
F. LYNWOOD GARRISON has reached Philadelphia, from
Colombia, where he inspected an important tract of dredg-
ing ground.
WILLIAM S. WEST is superintendent of the Wild Goose
company's operations on Ophir creek, in the Council dis-
trict, Alaska.
WALTER W. WILSON is moving to Austin, Nevada, to take
charge of a large consolidation of old mines, known as the
Austin-Manhattan.
JOHNSON & ENOS have moved their offices from the Tur-
hide hotel to the Quirk Bldg., corner of San Francisco and
Cinci St., Mexico City.
DAVID GOSHALE has resigned as manager for the Campanila
Minera Rio Tinto Mexicano, in Chihuahua, and will reside
at Berkeley, California.

ARIZONA.

ELDORADO COUNTY.

The Woodside Eureka Mining Co. has completed the work of sampling the vein in the recently unwatered Eureka shaft and are now building an engine and boiler house. The Woodside shaft, a thousand feet south of the Eureka, may be unwatered, at least a number of people in Georgetown are anxious to invest in such an undertaking.

On the Jumbo group of mines the Connors' adit is being re-opened and will be run ahead about 200 ft., from where a raise of 100 ft. will connect with the shaft on the Silver Plick ground, sunk by the Kockel Bros. in 1902-3, from which considerable doremen rock was taken. Everson, Klitch, and Jerrett, of Georgetown, are the owners of the group, and R. W. Klitch will have charge of the work.

The Bishop Creek Gold Co. reports that the drift being driven from the 160-ft. level of its new shaft has cut an orebody which assays about $170 per ton in gold. The drift is in only 35 ft. The shaft passed through good ore nearly all the way down, and prospects for a producer seem to be bright.—The accidental discovery of bonanza gold ore near Sliver Lake at the head of Rush creek, about 30 miles from Bodie, last week, has started a stampede into that district. Over 200 people are already on the ground and others are arriving daily. Stores and saloons are going up and business is flourishing in the new camp.

MARIPOSA COUNTY.

The Saxton Creek mines, 12 miles above Bagby on a branch of the Merced river, have been sold to Charles Morrell, who recently bought the Eigenbott. The consideration was $18,000, and the contractor calls for starting development work within 10 days. A stamp mill will be built.—The old Ferguson mine has been bought by a company which will resume work in October. This mine is on the same belt as the famous Hite Cove, being three miles northwest of the latter. It has been a great producer. Power for its operation will be taken from Merced river.

nevada county.

(Special Correspondence).—Manager Scarfe of the South Yuba Water Co. has officially notified the various mine managers in the Grass Valley and Nevada City districts that after October 1 only one-half of the usual supply of water will be furnished. The continued dry spell has made serious inroads on the water reserve and there is no prospect of an early relief. As a result several of the mines will be practically compelled to suspend operations, while others will operate on a greatly reduced scale.—The Woodberry mine has been bonded to a company of local men and will be worked on a comprehensive scale. A hoist and pump will be immediately installed and the shaft sunk to considerable depth.—The Santa Barbara company which recently bonded the Norambagua mine has made the first payment of $5000 on the bond. Foundations for the hoist, compressor, and other machinery are nearing completion.—A drift has been driven from the new shaft at the Alaska and has tapped the old shaft at the 300-ft. level. As soon as the shaft is drained active developments will be commenced. George St. John is superintendent.—An agreement has been effected between the Tarr Mining Co. and the New York-Grass Valley Co. whereby the latter will receive sufficient water to operate its machinery. One of the pumps is working, but the larger pump at the 300-ft. level is under water and refuses to work.—Ground is being broken at the Canada Hill mine for a five-stamp mill. Later on five more stamps will be installed. A large quantity of ore has been opened up. A. Charonnet is superintendent.—The Golden Crown mine will shortly resume work. Two stamps will be placed in commission.—A. M. Gilbert, of Santa Barbara, has opened a mine in Deardonville. Arrangements have already been made for the opening of the boarding house. Morgan Thomas will continue as superintendent at the mine.—Work is about to be commenced on the actual construction of the Niagara mill, at French gulch. The timber has been on the ground for some time. The contract for its construction was let the past week to Whitlock & Love, the Kennett contractors. It will be a ten-stamp mill.—O. W. Mansley, of Los Angeles, has taken a bond on the Copper Crest mine, near the Mammoth, owned by I. O. Jilson. Mr. Mansley is extensively interested in the operation of mines in Mexico and expects to give the Copper Crest a thorough development.

TOLUCA COUNTY.

The Laura and North Star mines have been bonded to W. G. Philips with an option to purchase within a year.
Colorado.

Clear Creek County.

(Special Correspondence.)—A compressor plant has been ordered by the Ramsell G. M. & M. Co., operating the Ramsell group of seven claims on Lincoln Mtn. The mill, which was partly constructed last fall, is to be completed without delay. This Company was recently re-organized, the bond of $10,000 having been lifted about six weeks ago. Funds have now been provided for continued development. The Market adit is to be advanced for the intersecting of the series of veins owned. The lode is in 325 ft., and the Golden Jack vein will be reached within 40 ft. Driving is to be started upon the east and west drifts of the Ramsell vein. This mill is to be equipped for both concentration and amalgamation. G. W. Teagarden has been re-appointed manager.—Work was resumed this week at the Culley adit, after a temporary close-down of two weeks. Driving was started on the Pineo vein cut 10 ft. from the portal of the adit. Within a few days work of advancing the adit will be put under way. The first known vein to be reached is the extension of the Jo Reynolds. A. L. Carr has been appointed resident superintendent.—A company is now in process of organization for the development of the Bonham group of claims, on McChlIan Mtn. B. O. Bonham, the owner, has interested a number of Philadelphia capitalists in the enterprise, and it is announced that work will be put under way within 30 days.—Extensive development has been started at the holdings of the Golden Glory T. M. Co., on Saxon Mtn. A plant of machinery has been ordered and the equipment is expected to arrive in two weeks. The preliminary work, such as reducing the grade of the adit, as well as re-timbering the same, has been completed. It is purposed to drive the adit for a distance of 10,000 ft. to intersect all veins lying along its course. The first vein is an extension of the American Sisters, and it will be reached within 150 ft. Enlarged work will also follow at the Drummond mine, operated by the same Company. The adit, now in 250 ft., is to be advanced, as a streak of $4 silver-lead ore is exposed on the hanging wall that is from 8 to 10 in. wide. The winze put down to a depth of 70 ft. is to be deepened, as the orebody in the bottom is 14 in. wide. This enterprise is being financed by Texas capitalists, and A. A. Hayden, of Denver, is manager.—Announcement has been made that extensive development will soon be started at the Honest John holdings, on Chicago Mtn. The adit is now in 2150 ft. and within 100 ft. the Marysville vein will be intersected. H. G. Fowler, of Denver, is manager.—The Kalamazoo adit on Republican Mtn. is being driven steadily forward. The work is somewhat slow owing to the fact that it becomes necessary to timber out the portal of the lower part of the rock. This adit is being driven for the express purpose of cutting the Snowdrift vein, which has the distinction of having produced the highest-grade ore ever mined in the Georgetown district. The vein will be intersected at an increased depth of 500 ft. under the present deepest workings of the mine, opening for exploitation a vast area of virgin territory.—Many of the operators and lessees have been holding up their advancing work, in advance of the price of silver. M. J. Riley, leasing on the Sunburst, was the first to start shipments, and is now keeping a jack-tram busy in bringing down a 100-ton lot of 200 oz. silver-lead ore.—H. C. Newton has assigned his bond on the Mollie Bawn and Bluebeard properties to C. F. Shaffer, of Denver, and it is understood that the full amount of $7000 will be paid during October. A company is now being organized and active development has been started. It is proposed to erect a 25-ton concentrating plant for the treatment of the low-grade ore that is exposed throughout the workings.—A new strike was made a few days ago in the Capital mines. In carrying a raise in the west drift of the Aetna vein a 3-ft. body of gold-copper-lead ore has been uncovered. Tests show the material to be worth 2 oz. gold, 7 oz. silver, 20% lead, and 25% copper. A higher shift has put on at the Pelican mill being operated by the Burleigh M. & L. Co. A hoist has just been put in for lifting the ore, that is being mined through the Burleigh adit, to the mill-hills.

Glipin County.

Hughes & Threewit have started up the Hughes mine, on Bellevue Mtn., under a lease and bond and have purchased a complete plant of machinery. The main shaft is now down 100 ft. and the lessees have also given a contract to Thompson & Hamby, of Central City, for the erection of a shaft building, work on which is to be advanced as soon as the lumber is delivered. Some excellent ores, both of the free-milling and smelting kind, have been taken out of the mine since its discovery.—Arrangements are being made for the extension of the lines of the Glipin Tramway Co. to the Anchor mine of the Hearne Gold & Copper Co., in Willis guich, and it is expected that grading work will be commenced within two weeks. When the tramway line is in it will permit of the ores being hauled much cheaper and it is expected that the daily product will soon reach 50 tons, as recent developments have opened good ore reserves.—A small force of men was put to work on the Russell mine near the head of Graham guich, in the Russell district, during the past week and Mark Harris is in charge of the operations. The Russell ores are mostly of the concentrating and smelting kind and it is expected that shipments will soon be commenced.—Denver and Eastern people are in-
MINING AND SCIENTIFIC PRESS

October 3, 1908.

interested in the Hampton Consolidated Mines Co., owning the Hampton group of mines in lower Russell gulch, and it is understood that money has been raised for the thorough development of the property, including the installation of a large plant of electrical machinery and the erection of larger buildings. The Hampton is known as a regular producer of enargite ores, carrying a heavy percentage of copper, the first-class ores carrying $50 per ton, while the second-class ores range from $20 to $30 per ton.

TELLER COUNTY.

The Carbondale Queen, on the west slope of Battle Mtn. at Cripple Creek, has been resumed shipments. The Big Four Leasing Co., which has a lease on the property, has recently completed a pipe-line from the Ajax and is now using power drills in breaking the ore.—Moore & Seeley, who have a lease on the Lucky Gus, of the Stratton estate, have received returns of 15 oz. gold on a shipment recently made from a 4 ft. vein at a depth of 460 ft. Shipments are being made at the rate of about 5 ton per week.

Gus Arnold, secretary of the Mine Owners' Association, has secured a sub-lease on the C. O. O. property, at the head of Poverty gulch, and is now engaged in prospecting.

The Columbia Mining & Development Co., operating on the Chickenhawk of the Kutkins company, on the north slope of Guyot hill, are loading out 16 cars per month of a grade of ore returning from 1 to 1½ oz. gold per ton. The company is breaking 1200 ft. of ore from the 300 ft. level where a vein four feet between walls is exposed. A considerable amount of development work is also in progress.

IDAHO.

SHOSHONE COUNTY.

(Special Correspondence).—The feature of the week in the Oeur d'Alene has been still another increase in the dividend paid by the Hecla mine, at Burke. A dividend of three cents per share has been announced, being the 63rd declared by the company, and amounts to $30,000. To date the company has disbursed a grand total of $1,046,000, of which $120,000 has been paid this year.—A strike of seven feet of good milling ore has been made in the adit of the True Fissure Mining Co.'s property in the Coeur d'Alene district. The property has been under development for the past 15 years, and the strike is said to have put it on an excellent basis.

Everything is now practically in readiness for the installation of the big hoist at the property of the Great Western Mining Co., in the Burke district. The last work on the new hoist will be finished within the next day or so, and the company will commence to sink on the orebody. It is the intention to sink to a depth of 200 ft. at this point, although it is believed good ore will be found within the first 100 ft. The annual meeting of the stockholders of the Temple Mining Co., was held last week, and the following officers were elected for the ensuing year: president, John Stambaugh; vice-president and manager, David Gross; secretary-treasurer, A. H. Peuthemonte; directors, C. R. Mowery, Herman J. Ross, Bonnell Michiavelli, and C. P. Morriam. The directors decided to continue driving and to keep up development all winter.—The property of the Aime Mining Co., in the Kettle Falls district, is reported to have been bonded to the British Columbia Copper Co., for $50,000. The terms of the bond provide that the property is to be extensively developed. A considerable amount of work has already been done, and although the mine has been an idle one time past the property has been practically idle.—Still another strike has been made on the property of the Black Horse Mining Co., in the Murray district. Like the former strike, the new one consists of between four and five feet of good milling ore. During the winter or early in the spring the Company will spend more than $100,000 on the erection of a concentrator and the installation of a form of machinery that will aid economical mining. As soon as the new railroad reaches the mine, shipments will be commenced.—It is expected that in a few months shipments will be resumed from the property of the Keystone Mining Co., from which more than $200,000 worth of ore has already been taken. The adit is progressing at the rate of 2½ ft. per day, and there is still about 200 ft. to go before reaching the orebody. The present adit will give a depth of about 360 ft., and if this comes anywhere near the expectations of the mine owners, the camp list may be expected to rise again almost immediately.—A report of the past 18 months' work on the property of the Trans-Continental Mining Co. has recently been issued to the stockholders. This report deals at length with the development of the mine, and is extremely favorable.—A force of men has been put to work on the property of the Evolution Mining Co., and it is reported that the number of shipments are about to be made from the property. This ore will be sent to the new smelter at Pend d'Oreille.—A splendid strike of ore is said to have been made in the property of the Montana Standard Mining Co., and while no details are yet to hand, it appears that this consists of 18 in. of clean shipping ore and several feet of milling ore.—Another contract is about to be let on the property of the North Franklin Mining Co., for a contract for 200 ft. of work having just been completed. The showing in the adit for the last 50 ft. is said to have been most encouraging; several stringers of ore have been cut and it is expected that the vein will be opened within a comparatively short distance.—A company composed of Wallace men has been formed for the purpose of taking over the Liquidation group of claims adjoining the Hecla mine, at Burke. The group consists of 13 claims, and has already been developed and a fair showing made. The new company is capitalized at $1,000,000.—Work has been commenced by the Tekoa Mining & Milling Co. on the Plumb group of claims, at the head of Dudley, Grouse, and Two Mile creeks. A contract has been let for 100 ft. of work, and after a short upper adit has been driven it is the intention of the company to drive a long adit. Work will be carried on all winter and an equipment of machinery will probably be installed in the spring.

Wallace, September 28.

KANSAS.

CHEROKEE COUNTY.

(Special Correspondence).—The Herald Mining Co. has started its plant after a shut-down of several weeks, during which time a considerable amount of repair and development work was accomplished. The incline shaft has been completed to more than 400 ft., penetrating the whole ore deposit. The plant was started last week and a turn-in has been made.—A three-compartment shaft is being sunk by A. O. Ihleman, on the Bing & Robertson lands, north of Galena. The shaft will open up the orebody found between 225 and 300 ft. A 250-ton plant will be built later.—The Chicago-Quapaw and the Good Luck mills are rapidly nearing completion, in the Baxter Springs camp, and will be ready for operation within a fortnight. Work on the Luckie mill is also being pushed as rapidly as possible. Arrangements are being made by the Hess O'Brien Co. to build a mill on its lease. The Indiana mill has been bought by the Consolidated Mining Co., of Miami, and is being moved to its lease on the land of the Baxter Royalty Co. near the Golden Hen.

Galena, September 19.

MISSOURI.

LAWRENCE COUNTY.

(Special Correspondence).—The output from the Aurora camp for last week was the largest of the year and the situation is encouraging. A large amount of prospect work is being done and good strikes are constantly reported. Three miles southwest of the city, a silicate strike was made on the Feaster land at 26 ft. A few drill holes put down there several years ago showed ore, but no further development was done until recently. A four-foot face has been opened, with ore still in the bottom of the shaft. The Snively & Co. have leased the Wheat and the Smith farms, southeast of the city, and will develop the land at once. Ore has already been struck, but further drilling will be done by Jim Moore. Ore has been found at 254 ft. with the drill still in ore when the work was abandoned. All the holes will be sunk to 300 ft. to strike the lower levels known to exist.—Grant Seburn struck a good run
of zinc-blende in a drill hole between the Sphalerite and the Cleveland-Aurora tracts. The ore was found at 35 ft. continuing for 32 ft.—South of Sarcoxie, on the Miller farm, ore was found from 57 to 75 ft. Practically the same find was made on the Wissau farm, two miles northeast of Ritchie. Across Shoal creek ore is being taken out at 25 ft. Outcroppings have been noted on the Connolly farm south of Ritchie. These strikes seem to indicate that a continuous vein extends between Sarcoxie and Ritchie.

Aurora, September 19.

NEVADA.

ESMERALDA COUNTY.

John LeFoe has secured a lease on the Gold Coin claim of the Jumbo Extension Mining Co., near Diamondfield. He had formerly a leasehold on the same block.—It is definitely stated that Nixon and Wingfield have secured control of the Combination Fraction, but that it is for their personal account and not for the Goldfield Co., Mines Co. The controlling interest comes through the purchase of the T. D. Murphy block of stock.—The Florence Consolidated Mining & Leasing Co. is steadily increasing its daily output of high-grade ore, and from present indications, will establish a record production before the expiration of the lease. The Company is shipping nearly 75 tons per day which will average more than $89 per ton. A large electric hoist will be installed within a few days, as well as an air-compressor, and as soon as both are in working, the output will be considerably increased. A cross-cut is now being driven to connect with the workings of the Baby Florence, and should be through within a week. This will insure better ventilation and enable the Company to make even greater headway.—The Nichols property, near Queen's station, is the scene of a new strike that is arousing interest in this old district. The Queen Canyon Mining & Milling Co., whose property adjoins the Nichols ground, is preparing to add several stamps to its mill and also install a cyanide plant. Re-organization of the Florence Gem was completed last week and the Company is now known as Florence Annex No. 2. The following new directors have been chosen: J. R. Woodbridge, T. H. Tighe, Charles A. Jones, Alfred Held, and Dix W. Smith. The basis of the re-organization was 600,000 shares for the holders of Gem stock and whose remainder of the million shares in the treasury. The lease runs six months from September 21. It has recently obtained an extension of territory and now has 250 by 300 ft., lying between the Baby Florence and the Engineers. Work has been started with two shifts of miners.—The mines of Goldfield produced during the week ending September 26 a total of 2371 tons of an estimated value of $135,750. During the same period the Tonopah mines produced 5242 tons of an estimated value of $141,225.

LINCOLN COUNTY.

The first consignment of the new stamp-mill for the Lloyd-Searchlight has arrived at Searchlight and is now being hauled down to the mine at Camp Thurman.—W. W. Hurt, of the New York Searchlight, has started work on several of his properties. The Waterspot claim is being equipped with a 12-hp. hoist. This will do service for considerable sinking and lateral work until the permanent new plant is installed and then it will be transferred to one of the other properties.—The Cyrus Noble mine has started a few men at work and it is believed that the force will be increased before long. E. H. Bryan, of Redlands, who with J. J. Pedertasg secured the property under foreclosure proceedings, is at the property and will have charge of the work.—The Loder gas smelter on the property of the Santa Barbara Searchlight Co., at Nelson, will be ready to blow in before many weeks and all are anxiously waiting to see its trial run. J. F. Loder, the inventor is now on the ground supervising the erection.

HUMBOLDT COUNTY.

George & English, lessees on the well known block of ground on the Fine Gold estate, have secured an agreement with the management of the Mazama Hills mill to treat 150 tons of ore from the lease, and stoping operations began last week on one of the ore-shoots in the lower adit.—The Lookout M. & M. Co. has been incorporated to work a lease on two promising blocks of ground on the Theriell estate. Fred L. Tyler, the moving spirit in the new Company, has been operating what is known as the Tyler lease, on the same ground, for more than a year, and has now secured a lease on the Pierce block. The two will be operated as one and extensive development started at once.

NYE COUNTY.

Construction work was resumed on the Campbell-Smith custom mill at Rhyolite last week, and the promoters of the enterprise expect to have the plant completed in a short time. It was to have been completed long before this, but a misunderstanding between the parties involved led to a suspension of operations. The machinery is now all on the ground, and it is stated that the work will be pushed to completion as rapidly as possible.—I. M. Williams, who has secured a two years' lease on the property of the Rogers Round Mountain Mining Co., has already started work, and is sinking a shaft. The terms of the lease require 350 ft. of shaft work. The Tonopah Mining Co. has declared a dividend of 25 cents per share, payable October 21. This is the second dividend this year, the first one having been distributed in July.—The Berry-Roche and the Chapman mills, at Manhattan, have reduced their charges for treating ore. The new scale is as follows: For ore worth less than $20 per ton the charge is $5, and for each additional $5 in the valuation of ore an extra charge of 40c. is made, the maximum charge being $8. It is reported that a company is to be known as the Bare Mountain Apex Mining Co. is being organized at Boston. The Company has strong backing and will take over the properties of the Norwich Consolidated Mining Co. in the neighborhood of Beatty. Several additional claims may be acquired if reports are satisfactory.

STOREY COUNTY.

Another old mine on the Comstock, the Crown Point at Gold Hill, is being rehabilitated. This makes two famous bonanza mines in operation there—Crown Point and Yellow Jacket. In Virginia City the Chollar, Consolidated Virginia, and Ophir are producing steadily, and the Ward and Union are in active operation. The Comstock is seeing a brighter day and presents a more favorable outlook for the future than in many years. Every month the actual output of the Comstock reaches many thousands of dollars.

WHITE PINE COUNTY.

The Nevada-United Mines Co., of Denver, operating at Ward, is shipping 20 cars of ore per month to one of the Salt Lake smelters. The ore is a sand carbonate, carrying 10 to 15% excess in iron and assaying from 40 to 50% lead and about 6 oz. silver. The vein is 20 ft. wide and the ore is shipped without sorting. It is highly probable that the Company will begin dividend payments at an early date.—A big strike in the Hole Card property, at Blackhorse, has greatly stimulated the interest in that field. The find was made in a 6 ft. shaft, the bottom of which is all in ore that pans exceptionally well. The Hole Card is owned by Boone Tilford, an old pioneer of the district, and by the Stephens estate, and is directly across the gulch from the famous San Pedro property.—F. B. Weeks has a force of men at work on the Fort Wayne group at Blackhorse, which he recently bonded. He has also leased the Whitney mill at Osceola, and will begin active work in getting it running order. It is rumored that the N. I. Desperandum, also at Blackhorse, will shortly resume operations.

UTAH.

BEAVER COUNTY.

W. M. Wantland, R. G. Wilson, and associates have secured control of the Iown No. 4, 5, 6, and 7, in North Star mining district, and will start active development at once. The property adjoins the Wild Bill, on which a depth of
300 ft. has already been attained and some good ore-bodies exposed.—The Cedar-Talismen Consolidated Mines Co. is to be organized to take over the interests of the Cedar and the Talismen mining companies in the North Star district. The capitalization will be 1,000,000 shares of a par value of 25c. 300,000 of which will be reserved as treasury stock and the remaining divided among the present shareholders of the two companies. The consolidation has not yet been ratified, but undoubtedly will be, because all those interested are in favor of the scheme.

MINING.

SOUTHWEST.

Nicholas Mining Co., of Nevada, is reported to have been reorganized as the Grant group, and is considered a very promising property. The ore is magnesite in grynhotte. The deposit is about 400 ft. long.—Work has been resumed at the Kimberley mine, near Golden camp, on Palmer Mtn. A shaft, which was sunk 100 ft., is being continued on the vein to the 200-ft. level. At that depth drifts will be driven on the vein preparatory to stoping. The mine is equipped with steam machinery and an air-compressor.

The Golden Chip Mining Co. has begun work on a group of copper bearing claims, on Kruger Mtn. The ore is of average quality, and the Company expects soon to have the property on a paying basis and to be shipping ore.—An immense bed of asbestos is reported 14 miles southwest of Twisp, said to be 400 ft. wide and traced 2500 ft. along the cropping. Specimens of long, white, silky fibre have been shown as average specimens. Several claims have been located by W. C. Johnson, of Seattle.

The Chelan Butte Gold Mining Co. has been organized, with capital stock of $1,000,000 divided into $1 shares, of which 400,000 have been placed in the treasury. The Company has taken over the Columbia, Butte, Little Butte, and Dakota claims, in the neighborhood of Lake Chelan. Considerable work has been done on the group.

SALISBURY.

The Boston Consolidated has started four additional units at its Garfield concentrating plant, making eight now in use. The capacity of the plant is now nearly 2000 tons of crude ore per day. The management of the Fortuna mine in Bingham has decided to try the leasing system and several blocks of ground will be set aside for that purpose. The Fortuna has a very creditable shipping record for both silver-lead ores, as well as copper, and for some time prior to the panic of last year it was a regular contributor to the local market. The mine is adjacent to the Ohio Copper Co.'s domain and has long been regarded as being an attractive property.

SUMMIT COUNTY.

At a recent meeting of the stockholders of the New York Bonanza Mining Co., of Park City, it was decided to recommend to the directors that the shaft be deepened to the 1000-ft. level. The officials which served during the past year were re-elected.—The Conkling Mining Co. has been formed to operate the Conkling and other claims at Park City, controlled by Col. N. Treweck and associates. The new Company is capitalized for 500,000 shares of the par value of $1 each, with 200,000 shares of treasury stock. Officers and directors of the Company are: Nicholas Treweck, president; William C. Hall, vice president; J. Leonard Burch, treasurer; George A. Land, secretary.

WASHINGTON.

OKANOGAN COUNTY.

(Special Correspondence.)—W. D. Greenough and two other mining men from Spokane, have been examining mines on Copper Mtn., near Chelan. It is reported that a deal of considerable importance is under way.—The Poland China mill is being overhauled.—The Molson Gold Mining Co. has elected a new board of trustees, with A. L. Norris, president; C. F. Rankin, vice president; A. D. Ord, secretary; W. J. Morey, assistant secretary; and F. W. Rankin, treasurer. The executive officers are all residents of New York. The Molson mill is being overhauled. The rolls are being replaced by stamps, and the capacity will be increased from 40 to 100 tons. It is expected the plant will be run steadily after completion of the improvements.—A large body of ore has been found in the Aztec group, in Chelan county, assaying 1.5% copper, 4.13 gold, and silver per ton. The Aztec, Homestead, Neutral No. 9, and Western Star claims compose a group under bond to E. P. Galline. The group is on the east side of Copper Mtn., on the same vein system as the Grant group, and is considered a very promising property. The ore is magnesite in grynhotte. The deposit is about 400 ft. long.—Work has been resumed at the Kimberley mine, near Golden camp, on Palmer Mtn. A shaft, which was sunk 100 ft., is being continued on the vein to the 200-ft. level. At that depth drifts will be driven on the vein preparatory to stoping. The mine is equipped with steam machinery and an air-compressor.

The Golden Chip Mining Co. has begun work on a group of copper bearing claims, on Kruger Mtn. The ore is of average quality, and the Company expects soon to have the property on a paying basis and to be shipping ore.—An immense bed of asbestos is reported 14 miles southwest of Twisp, said to be 400 ft. wide and traced 2500 ft. along the cropping. Specimens of long, white, silky fibre have been shown as average specimens. Several claims have been located by W. C. Johnson, of Seattle.

The Chelan Butte Gold Mining Co. has been organized, with capital stock of $1,000,000 divided into $1 shares, of which 400,000 have been placed in the treasury. The Company has taken over the Columbia, Butte, Little Butte, and Dakota claims, in the neighborhood of Lake Chelan. Considerable work has been done on the group.

A contract has been let to run an adit 300 ft., to cut the vein at about 200 ft. below the surface workings. The vein is rich in gold and, it is believed, will be a big producer. The headquarters of the Company are at Chelan.

—A steam engine and air-compressor and full equipment of power drills have been installed at the Holden mine, on Lake Chelan, and air-pipes have been laid to the No. 2 and 3 adits. Two shifts are employed on those drifts. Work is being kept going day and night in the No. 1 and 2 adits, and a good grade of ore is being broken. This property is owned by the Holden Gold & Copper Mining Co., of which J. P. Graves, of Spokane, is president. It is stated that activity on this property will be largely increased as soon as the Spokane & Inland railway reaches it, and heavier machinery can be laid down at reasonable rates.—The Chelan Consolidated Copper Co., operating four miles west of Phelps creek, has driven an adit 2000 ft. deep and intersected three veins which are from 4 to 10 ft. wide. Some of the assay returns from samples are reported to be large. One vein of white quartz, over 50 ft. wide, has been traced over 1500 ft. across the mountain.

Chelan, September 24.

CANADA.

BRITISH COLUMBIA.

Frank H. Cook and M. M. Johnson, of Salt Lake City, have secured a bond on the Golden Pawn group of claims on Sheep creek, 12 miles from Salmon, the sum named in the bond being $40,000. It is reported they have agreed to expend $2500 per month on development work. They have gold ore in quartz and quartzite which runs $50 to $150 per ton. The Nugget, an adjoining property, belonging to W. B. Pool, George Wells, and A. F. Grayce, of Nelson, has shipped ore to the value of $24,000.
Special Correspondence.

LONDON.
The Dull Season.—A Favorable Time to Develop Copper Properties.
—British Butte Mining Co.—Announcement of Extraordinary Gold Content in Placers.—Rhodesian Mines.

The latter half of August and the whole of September are always quiet periods in the City of London, and nothing but bare routine work is done. Everybody is holiday-making. No board meetings or shareholders' meetings are held. New business is not undertaken or discussed. The financial papers shrivel on the floor before winter sets in, and it is not a good time for London correspondents of American papers. In fact, I feel inclined to follow the example of the late Sir Stafford Northcote and give a lecture on 'Nothing.'

The last six months or so has been the dullest time for a good many years. The fall in copper, lead, silver, and tin has been fatal to new ventures, and in consequence of this more difficulty in securing employment is experienced by mining engineers than has usually been the case. Even members of eminent firms, and eminent individual mining men, are waiting for something to turn up. The stock exchange feels the absence of business, and members are occupying themselves in a sort of hopeless effort to stir up a boom in South African gold shares. There seems to be no chance of such a boom succeeding. Though the monthly output is advancing, the element of chance makes the situation attractive is absent. The Rand industry is too well established, and its methods and possibilities too well known, to evoke enthusiasm for the future. Old established mining businesses, like Rio Tinto, boom with the rise in copper. There is no rise in the price of gold; hence established gold industries don't boom. A few weeks ago I noted the appearance of a certain new company, and an announcement that capital was once more becoming available for new mining operations, but this was premature, as the flotation was not a success. Many promoters and moneyed men say it is no use to open up new copper deposits while the price of copper is low. Several prospecting and development companies have recently suspended operations on copper properties for this reason. It seems, however, that the period of low prices is the best for the preliminaries of operations. It takes a long time to get a copper deposit into shape for shipping or smelting. The new company that is ready to profit by a boom in prices is the one that wins, and the company that awaits a reviving market is likely to be ready merely in time for the next boom.

An American mining concern, having a London office and following is the British Butte Mining Co. It was registered under the laws of Montana in 1906 for the purpose of working the Blue Bird placer deposit at Butte, Montana. According to a statement made at a meeting held in London last year, the working capital was £30,000. A circular issued this week states that the placer has been thoroughly prospected by means of bore-holes, and that a shaft has been sunk 550 ft. below which a bore-hole has been driven another 300 ft. A cross-cut at the bottom of the shaft has been extended 975 ft., partly through placer ground and partly through granite. According to the reports, all the drill-holes and workings show the presence of gold, varying from 30 cents per cubic yard upward. It is intended to work the upper 45 ft. by means of dredges, one of which is to be on the ground before winter sets in, and nine more are to follow later. The deeper parts of the placer are to be treated by cyaniding. The excavation is to be by open-cut and effected by steam-shovels. The scheme is to eventually have a large plant that will handle 20,000 cubic yards per diem, and the cost is estimated at 20 cents per cubic yard.

During the last two months I have given some details of various Rhodesian mines, more particularly the Wanderer and the Selukwe. This week the latest details relating to the Globe & Phoenix are to hand. Those properties are situated in the Sekabwe district, 140 miles north of Bulawayo.

The company was formed in 1892 and milling commenced in 1900. For some time the Globe was the more profitable, but this mine is exhausted, and operations are now confined to the Phoenix. The most noteworthy point is the great depth at which work is being done, namely, 2900 ft. In spite of the increasing difficulties, the cost of mining is being reduced. During the first six months of this year the mill crushed 34,546 tons and produced 15,617 oz., which realized £56,590. In the cyanide plant 25,614 tons of sand yielded 2225 oz., worth £924, and 11,053 tons of slime produced 963 oz., valued at £4968. The total yield was 18,810 oz., valued at £77,539. During the 12 months of 1906 the total yield was 29,791 oz., so that production is well maintained. Any decrease is due to the fact that the extraction in the slime-plant has not been efficient, owing to the presence of sulphides and antimony. For some time the results were so poor that the slime was stored and allowed to oxidize, after which the extraction improved wonderfully. Although the storage and re-treatment involved two handlings of the material, the increase in the extraction from 40 to 90% made up for this extra cost, and in future it is probable that the total extraction will be permanently improved. It is interesting to note that the total extraction since the commencement of operations in 1906 has been worth £1,381,650, and the operating expenses £805,631, leaving a gross profit of £591,019, exclusive of depreciation, office expenses, and other incidentals. The total costs during the half-year were £90,550, including mine development, but not including depreciation and London office expenses, leaving a gross profit of £25,475. The costs work out at £1 8s. 11d. per ton, as compared with £1 8s. 1d. during the year 1907. The economy has been in mining, which has been reduced from 8s. 6½d. to 7s. 2½d. Mine development is charged 48s. per ton. Development during the six months has opened up additional bodies of ore, and the reserves have been increased from 107,209 tons on December 31 to 122,618 tons on June 30, and the average contents have increased from 11 to 12½ dwt. per ton. The directors have declared two dividends of 5% so far this year, the amount thus distributed being £20,000. The total distribution to date has been 16½% on the capital of £200,000, but it must be pointed out that this is not the usual return to shareholders, for 50,000 of the £1 shares were issued at £2 and 25,000 at £1. These high premiums were obtained in 1895 and 1899, when Rhodesians were booming. The present quotation of the shares is about 16 shillings. The township on which the mine
stands rejoices in the name of Que Que, which is as eupho-
nous as your Oshiosho and Shidoo.

I have referred lately to the great depression at the vari-
sic silver-lead mines of Broken Hill, in New South Wales, and
have recorded that one mine has closed down and that
others have had their profits annihilated by the low prices of the
metals. The North Broken Hill mine just issued a report for the half-year ended in June. Though the prof-
its have been much smaller, the company does not appear to
have been hit so hard as some of its neighbors. The
mine is improving and is becoming one of the most im-
portant of all in the district. For the half-year in question a
working profit of £33,407 was made and £14,000 distributed
as dividends, being at the rate of 10% on the capital of £140,000,
the remainder being partly kept in hand and partly written
off for depreciation. A year ago the distribu-
tion was £35,000. The ore treated during the last half-year
amounted to 65,033 tons, assaying 15.32% lead, 6.49 oz.
silver, and 1.6% zinc. The lead concentrate produced
weighed 11,003 tons, assaying 70.3% lead, 20.6 oz. silver, and
2.3% zinc. The recovery was 75% of the lead and 56.5% of the zinc. The zinc produced amounted
to 33,223 tons, assaying 4% lead, 3.67 oz. silver, and 15.2% zinc. This is sold to the De Bnevay Company, whose flota-
tion plant adjuncts. The orobodies are opening up in a
remarkable fashion and the reserves exceed a million tons.

**BUTTE, MONTANA.**

**New Troubles from Fires in Anaconda and St. Lawrence Mines. — Pennsylvanian Mine Resumes. — Pilot-Butte Shaft to be Deepened.**

The State Board of Railroad Commissioners has made an
order directing the Northern Pacific Railway Co. to reduce
rates on ore shipments from all points of Montana to Butte
and East Helena. The rate reduction amounts to 2.5% on
shipments to Butte and 17% on shipments to Helena. The
same order will soon be issued to other roads. Hereafter
freight rates on ore have been practically prohibitive for
small operators throughout the State. At the hearing be-
fore the Commission, the railroads, admitting the injustice
of their rates, offered a reduction of 25%, but the shippers
demanded a reduction of 41%. The conclusion reached by
the Commission is evidently a compromise. It is anticip-
ated that ore shipments will increase greatly as a result of
the reduction of rates.

The danger of a coal strike in Butte has probably been
averted by a temporary adjustment of the coal strike trou-
bles in northern Wyoming. The miners of three of the
large companies operating there have accepted a proposi-
tion to return to work pending a settlement of their griev-
ances. In southern Montana, however, the miners are
still out, and it seems to be the determination of the Union Pacific
and Amalgamated Copper Co. to fight the trouble-
out. The Montana operators insist on a reduction in the
wage scale and the miners refuse to accept a reduction.
The present schedule expires October 1.

With the exception of the interruption to mining in the
Anaconda mine by the existence of gas, all of the prop-
herties of the Amalgamated Copper Co. are again working. In-
trusions from this gas have been becoming more fre-
quently during the last six months, which seems to indicate
that the fire is growing more serious. Fire has been burn-
ing in the Anaconda and St. Lawrence mines since 1889, and
all efforts to extinguish it have been futile, as the fire feeds itself on the sulphide ores. The portion of the
mines where the fire prevails has been flooded, and bore-
holes have been put down from the surface, through which
streams of water have been run, but it has had no effect
on the fire. The only effective measure was to wall the fire
in with cement. But it often breaks through somehow,
or a crack in the rock permits the gas to escape. It is
often impossible or difficult to find the leak, and it breaks
out or appears in unexpected places and the miners are
driven from the mine. A little of the gas is sufficient to
prevent men from working. The latest outbreak was
choked in the shaft, and during the shut-down some mining
was done through the St. Lawrence and Neversweat shafts,
both of these mines being connected with the Anaconda.
In the latter case about 500 men and hoists about 550 tons
of ore per day.

The resumption of operations in the Pennsylvania mine
adds materially to the production of the Butte Coalition.
The Boston & Montana, under a mutual agreement,
mines jointly-owned orbedodies known as the Red Penn, in
which the Butte Coalition has a 40% interest. The ore is
high-grade. The Butte Coalition Co. is mining 900 tons
Copper ore a day by doing much development, principally
from the new Tramway shaft, though the Ramus mine is
also being opened on lower levels.

The Pilot-Butte Copper Mining Co. will not abandon the
Pilot claim, but will resume work on it shortly. The shaft
will be deepened to possibly 2000 ft. This was decided
on at a special meeting of the stockholders held at Mil-
waukee last week. The mine adjoins. The orobodies are opening up in a
remarkable fashion and the reserves exceed a million tons.

Orders have been received to prepare for a resumption of
work in the East Butte Co. mines, and Superintendent
Vall is engaged in unwatering shaft No. 1 and the lower
workings. The main shaft is 900 ft. deep, and it will be
sunk to 1500 ft. It is unlikely that much exploration will
be done above the 1500-ft. level, although there is ore all the
way from the surface to the 1500-ft. level. It is expected from Duluth that the North Butte Co. is
making plans to sink a second shaft. It would seem that
the most likely plan would be to sink the Berlin shaft, which
the Company contemplated doing a year or so ago.
Levels are being opened from the Speculator shaft into the
Berlin ground. The Speculator shaft is taxed to its utmost
capacity when 1300 to 1500 tons of ore are hoisted daily.
There is enough ore in sight to justify a daily output of
3000 tons, and a production of 50,000,000 lb. of copper per
year, which the Company could do with two working shafts.

Butte stockholders of the Davis-Daly Estates Copper Co.
have received official notice of the action taken at the recent
meeting toward the organization of a new company, to be
known as the Davis-Daly Copper Co., and provision for
the exchange of stock on the payment of $2 per share.

The September copper production by the Butte mining
companies aggregated 29,055,000 lb., against 26,121,000
in August. The total ore tonnage was 387,600 tons, against
355,500 tons in August. The average daily output of ore
and copper yield per ton, and the average daily copper pro-
duction for the 30 days of September were as follows:

Although the production of copper by the Amalgamated,
North Butte, and Butte Coalition companies is gradually in-
creasing, it is generally admitted by the producers that
business conditions and the copper market are not
improving as rapidly as had been hoped.

William Rockefeller and other members of the Rockefeller
family, with several stockholders of the Amalgamated,
had had no opportunity to look at the great copper mines from which the Rockefeller
family is drawing big dividends. Benjamin B. Thayer, as-
sistant to President Rogers of the Amalgamated Co., com-
pleted his inspection of the Amalgamated mines, smelters,
and other properties in Montana and returned to New York last week.

The Trenton Co. has finished sinking on the Gagnon shaft for the present and is engaged in cutting a station at the 2300-ft. level. The station is about half completed, and, when finished, cross-cutting and driving will be started. The vein is not far from the shaft, and should be reached in a few weeks. The work of sinking on the Little Mina by the Parrot Co. was completed. At the Parrot mine the cross-cutting at the 2100-ft. level has been rather slow work. It had been estimated, when work was resumed in the cross-cut, that the vein would be reached during the first week in September, but it is now said it will be several weeks before it is cut.

John D. Ryan, one of the directors of the North Butte Co., is quoted as saying that the North Butte has so much high-grade ore that it is possible to get average shipments below 5% copper, and that the average yield of copper ore mined at present is about 100 lb. per ton. The estimates of the officials of the Company vary. In Butte it has been claimed that the average is 120 lb. The average for September, as for August, was a little under 100 lb. The retirement of George Wesley Davis from the board of directors of the Davis Daly Copper Co. is taken in Butte to mean that E. Augustus Heinze and his close assistants are no longer in control of the Company, although Mr. Heizne remains the nominal head. The properties of the Company are practically idle, awaiting funds under the re-organization. Butte stockholders are not very enthusiastic over the $2 assessment as a basis of stock exchange. The Barnes-King Development Co. continues to earn a little money above expenses. The bullion receipts for August, according to the report of Mr. McGee, were $10,345, and the expenses amounted to about $32,000, including the cost of development and prospecting. If the Company continues the rate of earnings of the past three months it may soon pay a small dividend. On a capitalization of $200,000 instead of $35,000,000 the Barnes-King might yet make good.

SALT LAKE, UTAH.

Closing of Tintic Smelter.—Railroad Buying Oil Lands.—Clark Smelter for Las Vegas.—Production from Mercure Mines. — Mascotte Tunnel of Ohio Copper.—Bos ton Consolidated Mill.—Denver & Rio Grande Improving Service on Bingham Lines.

The closing of the Tintic smelter last week will have the effect of greatly reducing ore-production from the Tintic district for a while. Metallurgists who have followed the construction of the plant are not surprised; in fact, the interruption has been anticipated. Two months or more ago definite plans were put forth. The one had to do with the representation of the company and the other with the matter of ample power-supply was over looked. An attempt was made to get along with service from the lines of the Utah County Power Co., which has proved to be in general inadequate, especially during severe storms. The smelting company, however, has contracted with the Telluride Copper Co. to bring in its lines; hence it will soon have sufficient electric energy in reserve to meet all contingencies. Patrons of the smelter have been notified to hold back ore shipments until the imperfections are overcome, which will probably be within a month. The Ajax, Uncle Sam Consolidated, Lower Mammoth, Colorado, Iron Blossom, Beck Tunnel, and Dragon Iron mines have, therefore, suspended production.

The Los Angeles & Salt Lake Railroad Co., has become interested in the development of the Juab oilfield, in the eastern portion of Juab county. One rig is in operation and a second will be soon. The opening of several good wells in this region would immediately settle the road's fuel problem. The 'Salt Lake Route' has no coal mines of its own, and in the past two or three years has experienced difficulty at times in obtaining a supply from other sources. Some of the trouble has been overcome by the installation of oil-burning locomotives, which are now operated from Milford westward to the coast. With oil supplied from Utah fields, the use of coal for fuel would be discontinued entirely.

Information comes from a reliable source that W. A. Clark is seriously contemplating the erection of a smelter at Las Vegas, Nevada, which is regarded as an advantageous position for ores from southern Nevada camps. It would be down-hill practically all the way from Tonopah, Goldfield, Bullfrog, Pioche, and other camps. Mr. Clark has seen the Tonopah & Tidewater road cut into the business of the Las Vegas & Tonopah branch, and with the completion of the extension of the Nevada & California through to Mojave, California, there is a further possibility of a loss of revenue to the Las Vegas & Tonopah. Engineer in the employ of the San Pedro, Los Angeles & Salt Lake visited Pioche recently for the purpose of obtaining figures on available tonnage, and it is said that they reported enough ore developed in the Pioche mines to warrant the erection of a large plant. The only discouraging feature found was the possibility of litigation between the Nevada Utah Mines & Smelters corporation and the Ohio Kentucky Mining Co., the joint owners of some of the best property in the district. Subsequent movements, however, indicate that an adjustment has been effected without resort to the courts.

The August bullion production of the Consolidated Mercure mines was approximately $79,000, a substantial increase over the previous month. Recent developments in the Tintic district of the Consolidated Mercure property are important. The Magazine vein has been cross-cut for 57 ft., and the ore assays, according to George H. Dern, the manager, about $6 per ton in gold. The ore from the old Mercure mine averages about $4.

Work is being pushed vigorously in the Mascotte tunnel, at Bingham, by the Ohio Copper company. Colin McIntosh, the manager, is thoroughly familiar with the property, and is receiving excellent results. The most remarkable was announced by about February 1. The Mascotte adit has not yet reached the main Ohio Copper vein, but it has been passing through good milling material for some time.

Four more units of the Boston Consolidated Garfield mill are in operation, and the remaining units are gradually being finished up and made ready for service. The plant is treating an average of 1900 tons of ore to the Garfield porphyry-ore per day, and the plant is running smoothly. The extraction this month has run considerably higher than in August. The saving will be about 74%, as against 71.8% formerly. Several cENTS per ton have been shaved off the cost of milling. Boston Consolidated ore does not concentrate as many tons into one as does the Utah Copper ore, owing to the heavier iron content. But this condition may change in depth. At present the Boston mill is putting from 16 to 18 tons of ore into one ton of concentrate, which runs from 19 to 21% copper. Utah Copper puts from 18 to 22 tons of ore into one ton of concentrate, which, assays from 20 to 24% copper. The Boston Consolidated is installing in its mill two 'Special' Byron Jackson turbine pumps, replacing pumps of different design. In a recent letter these pumps were wrongly referred to as 'beside' the type made by the Adolph Jackson Co. There is evidently serious doubt in regard to the Denver & Rio Grande Railroad Co. being equal to meeting the demands to be made upon it, unless it provides more motive power for its Bingham lines, something it has been slack about doing in the past. But the officials have awakened to the fact that unless something is done to improve the service there will be a serious loss of revenue from the Garfield, which will be the natural consequence. This has been made apparent by the activity of the Utah Copper Co. in making recent purchases of rights of way for the proposed extension of its own line from Bingham to Garfield. The Bingham & Garfield Railroad Co., organized some months ago, took over all the rail lines and equipment owned by the copper company, consisting at the present time of about 15 miles of track, all of which is in service. It would have to build about 16 miles additional to reach the Garfield concen-
JOHANNESBURG, TRANSVAAL.

Main Reef Outcrop Extension.—Open Prospecting.—Government Accounting for Prospectors.—Rand Mines Expenses.—Mine Signaling.— Rhodesian Wages.— Mines Department and Shady Schemes.—Prevention of Fraud.

An noted a few weeks ago, the eastern part of the Rand presented a development meriting close attention by reason of the rich strike made in the vertical shaft of the Brakpan mines. The high assay value and big width of ore are being maintained in the drifts. But during the last two weeks public interest has been drawn to the other extremity of the Rand, some 40 miles to the west, where the extension of the Main Reef has shown a strange eccentricity. The last mine on the Main Reef (assuming the Botha reef, Randfontein reef, and Main reef to be the same) has extreme west is the Stubbs Randfontein. South of this, the series had not been found. On the dip of this property lies the South Randfontein Deep, always regarded as a 'deep-level'. It has been found, however, that instead of containing its normal north and south strike, the Leader and West reef worked in the Randfontein mines turns sharply to the east and thus converts the supposed 'deep-level' into an 'outcrop' mine. As yet little has been done upon the new strike, but the American engineers of the Newmann & Georz groups (Thompson & Cameron) have been able to issue a favorable report upon the outcrop occurrence, which shows good ore. That outcrop prospecting should today be proceeding upon the Main Reef within the area of the Witwatersrand goldfield would be as relieved as possible by any engineers acquainted with the locality, without such specific explanation of this erratic turn or throw of the formation.

With the exception of the pseudo-dramatic outbursts of Mr. Wybergh, formerly Commissioner of Mines, and now a self-styled champion of the people, who has asserted that the Precious and Base Metals Bill was the outcome of a conspiracy between the land-owners and the mine-owners on the other, the most notable recent Parliamentary discussion upon matters pertaining to the industry has been that connected with 'open' prospecting. Mr. Wybergh's financial friends have persistently advocated the introduction of a policy of open prospecting with all vigor, but the weightiest arguments in the world appear to be of no avail against the stubbornness of this Government, which is so strongly established as to render further explanation of its policies superfluous. According to the new bill, prospecting can be carried on upon proclaimed crown land, on all unclaimed crown land, on unclaimed private land "on the written request of the holder of the mineral rights," and on unclaimed private land on which no bona fide prospecting and mining title for agricultural operations are in progress. Drummond Chaplin moved an amendment providing for a widening of this field in accordance with the principles he has long advocated on the platform and in the press. Thoroughly to appreciate the justice of his wish to see every farm open to the prospector, after giving three months' notice to the owner, one should possess a knowledge of the value of the average Transvaal farm (perhaps about 5000 acres) and the very small proportion utilised for agricultural, pastoral, or other farming purposes. Moreover, even if the prospector were such a destructive individual as the spokesmen of the farming interest like to suggest, his attentions would certainly be more generally directed to the rocky parts of the land where exposures of formation occur and led to the granite walls, covered with a clothe of subsoil. A side issue has been raised in the declaration that a community of good prospectors does not exist in the Transvaal. Obviously, the cause of the lack of experienced men has primarily been due to the absence of opportunities, and it may assuredly be declared that men of the right sort would arise, as in Rhodesia, upon the provision of reasonable inducements. With characteristic stubbornness and lack of foresight, the Dutch leaders are determined, however, to oppose the policy of open prospecting.
It is satisfactory to note that the Minister of Mines has arranged for the assaying and analysis of minerals for prospectors and others, at moderate fees. It is specified that the special facilities are offered only to those who, in the opinion of the Minister, are worthy of assistance. The tariff includes the following charges: gold, 6s.; gold and silver, 7s. 6d.; silver, 6s.; copper, 6s.; tin, 12s. 6d.; lead and zinc, 7s. 6d.; lime and magnesia, 7s. 6d.; iron, 7s. 6d.; arsenic, antimony, nickel, cobalt, manganese, bisulphur, or mercury, 19s.; chromium, tungsten, vanadium, or molybdenum, 15s.; platinum and allied metals, 17s. 6d.; complete analysis of coal (Thompson's method), 21s.; and coal, evaporative power, 5s. Samples can be sent by rail free of charge from the Rand Deep, and must be accompanied by an accurate description of the locality from which they have been taken. As usual, the Geological Survey continues to identify minerals, under reasonable conditions, free of charge. The services rendered to the prospector in this direction are certainly considerable, but the stimulus given to the mineral exploitation of the country by these concessions would be quite insignificant in comparison with what might be done if the Government adopted the policy of 'open' prospecting.

The quarterly returns of the Rand Mines subsidiaries, in their customarily analytical form, provide an informative statement as to the present working costs upon the best managed deep-level mines. The group includes deep levels of various types—Darwin Roodepoort Deep with its narrow gold-carrier, the wide veins of Crown Deep and Rand Deep, and the much faulted Nourse mines. Their stamp-mills range from 60 to 290 heads. The analysis of results disclose the following: stamp-duty per diem, 5.82 to 7.97 tons; mining expenses, 10s. 8.96d. to 17s. 4.93d. per ton, with an average approximating 13s. 5d. per ton; reduction expenses, 5s. 8.9d. to 5s. 2.3d., with an average of about 4s. 3d. per ton; total expenses, 16s. 11.2d. to 25s. 8.3d. per ton.

Various systems of mine-signaling have been under discussion of late, and several electricians and engineers have been exerting their ingenuity to devise a scheme calculated to reduce the chances of mishap due to the actions of irresponsible persons (a contingency of special importance in mines employing so many unintelligent native laborers), to negligence on the part of the driver or brakeman, or accidental electric contacts. The whole question has been brought to a head by three papers read before the Transvaal Institute of Mechanical Engineers. One of the authors, G. T. Plumb, advanced the opinion, as the result of wide investigation, that the three-way parallel system, at present most commonly in use, offers the most advantages for the following reasons: (1) simplicity and few failures are required, making for efficiency and economy; (2) signals are simultaneously given on all levels, which keeps all persons concerned in touch with the work going on; (3) it prevents the driver from getting a confusion of signals; (4) all signals are transmitted to where the onsets is working, so that in the event of any authorized person working the case or slip, he is notified and can attend to the matter. Mr. Plumb therefore considers all systems communicating with the onsets alone; also the practice of locking-up or cutting-out bells, which have, when readily accessible, often been the means of saving life by the opportunity provided for a prompt signal to stop bolting or lowering. He declared that many mines neglected to keep their signal apparatus, above all, in a proper state of efficiency; according to Government regulations, however, a weekly inspection should be made.

Profiting by the surplus of skilled miners available today in South Africa, due in part to retrenchment at Kimberley, a 29% reduction in the standard scale of wages has been arranged by the Rhodesian Chamber of Mines. Though naturally causing dissatisfaction, the inevitable has been accepted by the miners without protest. The prospect of those refusing to work under the new scale have been readily filled. According to the new agreement, the principal mines are now paying as follows: miners and timmermen, 18s. 6d. to 20s. per shift; underground shift-houses, 22s. 6d.; machine-men, (2 drills) 22s. 6d. and (3 drills) 25s. per shift; engine-drivers (hauling), 20s. per shift; carpenters, fitters, smiths, etc., 21s. 6d.; amalgamators, 20s. per 8-hr. shift, and cyanide shift-mens, 17s. 6d. per 10-hr. shift.

Whether the Government, through its Mines Department or Geological Survey, should closely follow the development of outside districts and issue reports upon new propositions, after the manner of the Australian and Canadian Departments, is a question open to much debate. Generally speaking, our official authorities have fought shy of publishing opinions upon new mineralogical occurrences in which the public have staked money, fearing charges of interference with private interests and so forth. Whatever the possible abuses of such investigation, the benefits as a rule must far outweigh them. As an example of such independent and disinterested report may be noted the recent exposure of a scheme in the De Kaap goldfield that has been wildly boomed by a firm of outside share-dealers by means of advertised reports and statements, to the cost of many gullible speculators. The mine used for the purpose of syndicate promotion is called the Verdiite—appropriately named, in view of the color of the steatite-schist worked and of the faith of its shareholders. Scrip has been run up to £2 or £4 on the strength of glowing reports. The Government has wisely published the information in its possession with regard to this property, from which it is learned that the spot was one of the first discovered (1885) in the district, that it has been worked spasmodically since that date, that the lenses (irregular and small) of gold-bearing ore yield only 2 to 5 dwt., and that the lenses which contain the gold are so small and erratic that it would be difficult to keep a mill, however small, running continuously on them, unless a large amount of development were done. The dump on the property, representing the rock obtained from the shaft and drifts in ore, is said to be too poor as it stands to be considered an asset or to repay crushing. Greater ingenuity than even the Transvaal promoter possesses must be exercised to reconcile the official report with the statements made by the directors. This matter is referred to at some length, as it tends to show the attitude of the public authorities to withstand with a new factor in sound Government inspection, and the liability of this inquisitive interference with the noble work of the pioneer (using public money) will result in checking many questionable ventures.

Map of the African Goldfields.
Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Standard silver nitrate solution for titration in determining free cyanide should contain 6.535 gm. of the nitrate to each litre of water.

The mean velocity of water flowing in a channel may be taken as approximately 0.5 of the maximum surface velocity, which latter may be determined by a float.

Steel which is too hard to file may be cut by the following mixture: sulphate of copper, 1 oz.; sl. 3/4 oz.; common salt, 1/2 teaspoonful; vinegar, 1 gill; and nitric acid, 20 drops.

The sensitiveness of a level is usually stated by giving the angle corresponding to a one-inch movement of the bubble. Good engineer's levels have a motion of 120 to 200 seconds per inch, or a radius of curvature of 140 to 85 feet.

Sizes of wood screws are given by a series of numbers. The diameter, D, may be obtained by the following formula:

\[ D = (N \times 0.01325) + 0.056 \]

in which N is the number of the screw.

The rating of air-compressors, when expressed in the number of rock-drills to which they are capable of supplying air, is usually based upon a consumption of a volume of air at 60 lb. per square inch pressure, or about 100 to 110 cu. ft. of free air per minute.

The standard boiler-horsepower, according to the Am. Soc. M. E., is an evaporation of 30 lb. of water per hour from a feedwater temperature of 100°F. into steam at 70 lb. gauge-pressure, which is considered equivalent to 34.5 units of evaporation; that is, to 34.5 lb. of water evaporated from a feedwater temperature of 212°F. into steam at the same temperature.

Vara is a Spanish measure of length of approximately 33 inches. It varies even in different parts of Spain, and has a different value in almost every Latin-American country. In Mexico the length of a vara is exactly 33 in.; in Colombia, 31.496; in Chile and Peru, 33.366; in Argentina, 34.122; and in Uruguay, 34.848. A vara is subdivided into centis, or fourths, which is a dimension more commonly referred to in Spanish countries than the pie or foot.

Reversal of the reaction, causing gold to re-dissolve after it has been once precipitated from cyanide solution upon zinc, is due to polarization of the zinc terminal, the electrolytic action between the zinc-gold couple accordingly being stopped. No remedy can be suggested without knowing the cause. The brittleness of the zinc shavings after exposure to the solution for some time may be due to precipitation of salts of lime or magnesia on the zinc-surface, or it may be due to the precipitation of copper. An analysis would be necessary to determine the exact cause of the trouble.

Mispickel is exceedingly brittle, and tends to produce a large amount of fine material when it is crushed, thus causing large losses in concentration. Hence, where the ore is 'bunchy' and labor is cheap, it pays to practice cobbing. Otherwise the ore should be crushed to the least extent compatible with the liberation of a quantity of the mispikel from its gangue sufficient to render concentration on a jig economical. The tailing from the jig should then be re-ground in rolls, classified, and the coarser product concentrated on jigs, and the fine product on some form of rifle-table washer.

Assessment work must be done manifestly for the benefit of the claims, and hence work done by other persons, or by an association of individuals, inclusive of the owner of claims which will benefit thereby, would not apply, unless such work were done upon the claim itself, and was clearly of benefit for the ultimate development and extraction of mineral. The construction of a flume for carrying water to work a claim has been held as inapplicable, except as related to that portion of the improvement which was directly upon the claim in question. It might be accepted, but it could be challenged, and might lead to litigation.

Normal sulphuric acid solution is made up by adding to 49 gm. H₂SO₄, an amount of distilled water sufficient to make exactly 1 litre of the mixture. Sulphuric acid being bi-basic, the number of grains taken to make up a normal solution is half the molecular weight. In testing for alkalinity in cyanide practice, samples of 30 c.c. are taken by the solution man, 2 or 3 drops of 1/10 phenolphthalein solution are added, and this is titrated with fifth-normal sulphuric acid. Each tenth of a cubic centimetre of the N/5 sulphuric acid used corresponds to a percent of free alkali in the solution being tested. In many plants tenth-normal acid is used, titrated into 100 c.c. of the mill-solution. In this case each unit or percent of free alkali indicated equals 0.056 lb. CaO per ton, or 0.112 lb. KOH, and 0.080 lb. NaOH per ton.

Erroneous location of a mining claim, resulting in the lode-line traversing the claim laterally, instead of longitudinally as desired, has the effect of restricting the locator to that length on the lode which corresponds to the width of the claim, that is, to a maximum of 600 ft. In other words, as construed by the courts in such cases, the originally intended end-lines become side-lines, and the side-lines become end-lines for purposes of determining the extra-lateral right. An amendment of such a location may be made at will, but in so doing the amended location becomes junior to all contiguous or neighboring claims, and cannot concede any extra-lateral right in conflict with those properly pertaining to them. The claimant, under such circumstances, may easily lose more than he would gain by amending.
Discussion.

Readers of the Mining and Scientific Press are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

Orebodies Without Walls.

The Editor:

Sir—For a long time in the history of mining the ‘true fissure vein’ was regarded as the standard of excellence in ore deposits, and an orebody without walls was viewed with uncertainty and sometimes with distrust. As experience extended, it was realized that many rich bodies of ore fell without the pale of this classification, but still, in many districts, the practical miner clung to the tradition, and often, hoping against hope, strained his imagination in the effort to find true walls in his property where none existed. At the present day, however, the successful exploitation of large orebodies which are clearly impregnations of country rock, and the realization that some of these are far more important commercially than many wall-limited veins, have led some successful operators to frankly declare that they are looking for properties in which the ore deposit has no walls, thus hoping to eliminate some of the commercial disadvantages of fissure veins, such as limited width or the restriction of the ore to shoots.

As the frequent occurrence of commercial orebodies in metasomatic shear-zones has become a matter of record, it is of interest to know how far such orebodies retain a uniform condition, and what variations in them are possible or to be expected. Since they are specially abundant in Sonora I give the result of my observations in that region, where the variations of importance to the miner are mainly as follows:

1. Diminution or cessation of ore with change of geological formation, as in passing from limestone to quartzite or from rhyolite to granite. In this type of variation is seen the chief disadvantage of an impregnation of country rock as compared with a true vein. In the latter the ore is in a continuous vein-stone, filling a fissure, and, continuing its character, independent of the rock-formation it traverses. In the former the amount of metal deposited is dependent on the selective power of the rocks through which the metallizing solution flows, or, in other words, the chemical power of the rock to precipitate the metallic compounds. This distinction was especially emphasized at Butte, Montana, where a difference in selective power was observed in two different varieties of granite. At Minas Prietas, Sonora, rhyolite has had a greater selective power than the underlying granite, which is nearly barren of ore as compared with the former. In the Altar district I have seen a shear-zone penetrating quartzite and limestone, in which the latter carried much ore and the former little. The latter case may, however, involve the quality of porosity or even of solubility.

2. Lateral off-setting through constriction of the zone of flow and change of direction. The effect of this is similar to that of a fault in a fissure vein. In the shear-zone, however, there is often no particular fissure or fault-plane which by its direction may suggest where the continuation of the orebody may be found.

3. Longitudinal constriction or limitation of flow. This results in shoots of ore similar to those in fissure veins. Sometimes when the ore is continuous such shoots occur as wider and richer portions of the metallized shear-zone. The shoots are sometimes separated by masses of shattered rock, barren of metal, and in the nature of ‘horse.’ Below and above the horse the shoots may unite.

4. Local deposits of quartz which at the surface resemble creppings of fissure veins, but which may be limited longitudinally and in depth, although the ore may continue horizontally and vertically. The limited extent of these quartz masses may discourage an inexperienced person, but the distribution of the ore is generally quite independent of them. As this class of deposits becomes better known and its variation and possibilities are classified and put on record, undoubtedly other variations will be made known.

Tailing Wheels or Pumps?

The Editor:

Sir—I have noticed from time to time that the South African mining companies are discarding tailing-wheels for centrifugal pumps, but, like W. L. Reid, I cannot see how the centrifugal pump can be compared favorably with tailing-wheels, either as to efficiency or cost of maintenance, especially where the entire mill product, both sand and slime, is to be handled. Neither can I see that it is necessary, as your editorial suggests, to parallel the tailing-wheel with some other mechanism to serve in emergencies, any more than it is necessary to have two systems of rock breaking at the head of the mill. The Tono-pah Belmont mill has two tailing-wheels, of the inside-bucket type. One measures 30 ft. over all, making 5½ rev. per min., elevating 200 tons of sand and 1200 tons of solution each 24 hr. from the battery discharge, and delivering to Huntington mills and concentrating tables, driven from a 7½-hp. motor, with three reductions of speed. The actual power consumed after starting is about 5 hp., figured at $8 per horse-power, making a cost per ton of 0.09 cent. The other is 48 ft. over all, making 4 rev. per min., elevating 200 tons of sand and 1500 tons of solution each 24 hr. from table-discharge to conc-classifiers at the head of the cyanide plant, driven from a 10-hp. motor with three reductions of speed. The actual power consumed after starting is about 6½ hp., figured at $8 per hp., making a cost per ton of 0.12 cent.

The experience here has been that the tailing-wheel is the only mechanism in the mill which has worked continuously during the life of the mill, 16 months, without any repairs other than the shortening of a belt, which was done while the mill was down, due to other troubles. With three 6-in. and
three 4-in. centrifugal pumps, handling Butters filter-stock solutions, and agitating slime, one man is kept busy during an 8-hr. shift each day, packing, repairing, and keeping the pumps in running condition, while the tailing-wheels will run with the regularity of an eight-day clock.

Tonopah, Nevada, September 23.

Lives of Mines.

The Editor:

Sir—Referring to the editorial affirmation, in your issue of September 26, that “the big money in mining is made by developing a young possibility into a profitable property,” it may be assumed that the intent was to limit the application of the advice to a class of deposits which are capable, as you say in the next line, of being “finally developed.” The Rand ‘banket’ may accordingly be taken as the type. The ‘big money’ is indeed made in the way you intimate—when it is made at all. Events of this kind are rare; that is precisely why we hear of all of them. In the aggregate the number is important, for the earth is big, and Nature has been fairly generous, but the sad stories of her coquetting with fortune-hunters fail of record and advertisement before the world. Men rejoice in success; they bow down to and worship it; they shrink from the contemplation of failure. Statistics are quite unavailable in support of contentions either way, yet the evidence is strong enough to command universal belief that more money is lost than won in developing prospects. Development companies almost invariably abandon the game of taking infant mines and rearing them in the way they should go. The infants are apt to develop ugly traits and lead the hopeful foster-parent into wasteful expenditure. To abandon similarly, the fact seems to be that a corporation, or a man of means, capable of undertaking large enterprises, wins success more certainly by paying someone else for his courage and luck in development than by taking these initial risks.

Your editorial comment is, in effect, a denial of the possibility of accepting mines as articles of traffic in accord with legitimate business principles. This seems to be a view originating in the pioneer attitude toward natural resources. Even virgin lands are a basis for gambling and wild speculation in the opening of new countries, and fortunes are lost and won in them before the conditions of rainfall, frost, drought, and soil-adaptability have been ascertained. The period of speculation encouraged by uncertainties is of comparatively short duration in colonization, but while it lasts it offers resemblances to the conditions which give to mining its unfortunate romantic character among the forms of human industry.

In the interest of sounder and safer methods, speculative features should be stripped from mining to the utmost possible degree. Mining should be rendered as safe as conditions will allow, and under intelligent technical and financial guidance an immense amount of risk may be eliminated. That should be the aim of all men having the interest of the mineral industry at heart; it has been the aim of the Mining and Scientific Press, otherwise there would be no reason for its existence. Belief in the possibility of lessening the speculative features in the exploitation of the mineral wealth of nations is the reason why geological surveys are instituted. Lingering disbelief in the feasibility of reducing the development of mining to a rational economic basis may be the reason why the legislators at Washington are so niggardly in their appropriations for the support of the Geological Survey. One of the disabilities under which mining labors in this country, and in all new countries, is that mines are not looked upon as possessing rational and reasonable market values. Coal lands are no longer a gamble. They are paid for at so much per acre, based upon proper discount of the future. Iron mines are appraised in the light of ore producible; copper mines have taken a far more dignified position in the commercial world than they occupied a few years ago. Men now appraise copper mines and fix the value of copper stocks with reference to the ore developed, rather than in fond reliance upon the glittering possibilities beyond the drill.

The point deserving emphasis is that mines should be regarded as legitimate assets, as properties having rational and ascertainable values. It is insistence upon the speculative feature which gives undue prominence to the 'possibilities and probabilities' figuring so high in promoters' prospectuses. The farmer is a gambler too; he gambles on the rain; he gambles on the blight, and the bugs, the state of the market, and the railroad rate. But the price of land strikes a level on the basis of the average crop. The manufacturer gambles on the future demand for his finished product, on the cost of raw material, on the stability of labor conditions, on the peril of new inventions, and on loss of the advantage of what at the moment is the latest type of plant. All human effort is in one sense a gamble. But we do well not to insist upon it. It is better to frown on the word 'luck': to exalt the intelligence that grapples with Nature and makes her yield to our control. 'Gambling is a hard word; it suggests the wrong thing for sapient men; and 'speculation' is its half-brother. We must, as far as we can, get down to business, and realize that the sanest endeavor is that which gives a fair equivalent. The vendor of a mine usually does not want to give a fair equivalent. That is why you, Mr. Editor, remarked, in what I assume was a fit of melancholic desperation, that "when a mine is finally developed, it is well to let the other fellow have the 'investment' while you look around for another 'speculation.'" This view is distinctly discouraging. If a man owns a good thing, but cannot develop it, he is doing a good stroke of business to sell it for what it is demonstrably worth, and no mine is worth more to a buyer than he is sure to be able to get out of it. This cuts severely across prevalent customs; nine-tenths of the so-called 'mining men' in America will rage at the suggestion; but ten years hence nine-tenths will think the other way, if the signs in the heavens are not misleading. The tendency is toward more and more sanity in mining. Even prospecting may become a matter of systematic scientific investi-
gation, as it has become in most of the European countries. All along the line the modern tendency, with the increasing application of expert knowledge to industry, is to eliminate the element of chance.

It is too much to ask even the editor to be consistent. It was Emerson who said that consistency was the vice of little minds. The response of the intellect to the passing show gives rise to varying opinions. So I am pleased to turn to your editorial of April 25 on the 'Yukon Gold,' and quote, "We do not ask whether the mining operations will be profitable, but whether they can repay the capital and a reasonable interest." That should be the rule applying to every mine. That is the rule which would guide an investor in a mercantile or manufacturing enterprise. To draw a distinction between mining and other forms of endeavor is to stunt the development of a noble industry which is based in the augmentation of actual wealth; it is to deny to it the sanity which gives dignity, and to lessen the value of engineering services in lifting it out of the realm of accident into the class of regulated industries. Several leading companies with widely scattered mining interests have been following closely the plan of paying no more for a mine than the net value of the ore developed. That rule even allows for a large element of chance in recovery of the invested capital, but it marks an advance toward commercial methods which is desirable for all concerned, for the prospector, for the promoter, for the investor, and for the engineer. In this connection it may be interesting to note that a class of prospector is becoming common, working upon a new principle, namely, that of 'large sales and small profits.' He goes at the business systematically. He not only invades the 'boom' camps, but he investigates the quiet camps. He has claims widely scattered, but selected judiciously, with a view to their being needed presently. He places no exaggerated value upon them. According to conditions, he may sell a claim for $500, for $1000, perhaps now and then for $5000, and rarely for a large sum. In this way he averages a good income. He is in mining strictly as a business, not as a gamble. This is another of the healthful signs of the times which everyone should greet with satisfaction.

Comerclante.

San Francisco, September 28.

Cost-Keeping.

The Editor:

Sir—I have an interesting letter in your issue of July 25, by H. E. West, on 'Cost-Keeping.' While my experience in mining is rather limited, I have had considerable experience in using and installing some of the various cost-keeping systems in contracting and engineering works, and I am unable to see why the same principles do not apply in both cases, as they are fundamentally the same, having to do with the management of mine and machinery to obtain a maximum output with a minimum expenditure.

I think Mr. West strikes the 'right ground' except where he says, "the ideal manager is he who, while never having to leave his office, yet is perfectly posted by daily, weekly, and monthly reports and cost sheets." I have never heard of nor seen any system of cost-keeping that would automatically supply the 'personality' of a successful manager. If it did, what would be the use of having a high-salaried manager when a cheap bookkeeper or clerk could do the work. In fact, I have seen few clerks who could install a successful cost-system, but they can often keep it in operation after it has been started. I myself have found it more difficult than designing, as it involves so many unknown quantities. The cost of maintaining such a system is slight, and it is almost the universal opinion of managers that it is a great help in managing a mine and helping to reduce the costs. So to speak, it places a 'boss' over each individual man and cuts out the necessity to work 'like blazes' when the boss is around, so as to be able to fill a pipe and 'swap yarns' when he is out of sight. It is a great help to keep up the output of individuals. It cuts down the expense of superintendence, often more than enough to pay its cost. It prevents padding the pay-rolls. It makes it absolutely necessary for the mine to keep the machines and tools in the best shape and to keep them moving, as any falling off from this source or any other will be quickly discovered. It enables the manager to analyze his expenditures with a view to improving his foremen, laborers, and plant, and it helps to determine a fair unit-price for similar work in the future. Great care should be exercised in using published cost-data unless the conditions are known. Lastly, it enables the manager to know early each day if his work for the preceding day has been carried on at a profit or a loss. If he knows he is running behind at the time he is doing it, he will have opportunity to improve conditions before they have gone hopelessly bad.

The records that the workmen or foremen have to keep should be very simple and involve practically no calculating. It will be found to be an advantage to have a printed blank on which to punch or check off the quantities as far as practicable. Most of them do not like to do much figuring. Most all the calculating should be done in the office by the cost-clerk. This last position is one of the most desirable for a young engineer who wants to get the run of the work. If I am not mistaken, it is used to be that anything outside of assaying, surveying, or draughting was beneath him, but now almost everybody recognizes that the commercial work, as a preparation for managing, is as important as any.

Chas. Kirby Fox.

Pomona, California, July 27.

Copper converters are universally side-blown, since bottom-blowing would oxidize the metallic copper before the oxidation of the matte was complete. Furthermore, the high specific gravity of the copper would require a higher air-pressure if the full head of molten metal in the converter had to be overcome.

In a new French Welsbach mantle, the rare oxides are consolidated in an electric furnace, greatly increasing resistance to shocks, tremors, and draughts.
RECENT CYANIDE PRACTICE IN KOREA.

Written for the Mining and Scientific Press
By A. E. Deucker.

The Oriental Consolidated Mining Co., with works situated in northwestern Korea, is now operating a total of 220 stamps, crushing about 30,000 tons of low-grade ore per month. There are five stamp-mills and four cyanide plants, scattered over the concession, using different methods of cyanide treatment, the most recent being the method employed at the Candlestick mill. The cyanide practice here is somewhat unusual and a detailed description may prove interesting.

At Candlestick the Company has a small mine that will produce 20 to 30 tons of $20 ore per day. The ore consists mainly of quartz, and contains from 10 to 20% of sulphides, including iron pyrite, zinc-blende, and galena. Unlike the other ores on the concession, there are no serious obstacles to cyanide treatment, such as the presence of argentaceous pyrite, mica-slate, and stibnite. The former two oxidize readily in moist air with the formation of ferrous sulphate, which decomposes cyanide, and also acts as a de-oxidizer, absorbing oxygen from the cyanide solutions. The ore is free-milling to a large extent (70 to 75% of the gold being amalgamated on silvered copper-plates). The greater part of the gold, however, is in a fine condition. There is an abundant supply of water for milling purposes throughout the year. Power is an inexpensive item, for both wood and water are plentiful, and close at hand.

After performing experiments on a practical scale at the Taraceol test-plant I decided that the most economical form of treatment for such an ore would be to crush with stamps, and use inside and outside plate-amalgamation, followed by direct cyanide agitation of the total tailing, with decantation and vacuum-filtering. Preliminary concentration before cyanidation is omitted.

The mill consists of one 7 by 10-in. Blake crusher. 10 stamps weighing 1050 lb. each, and two standard 10-ft. silvered copper-plates in three sections, with drops of 1 1/4 in., and a grade of 3 in. to 1 ft. For inside amalgamation there are two plates, both back plate and chuck-block. Also there is included a clean-up pan, and all necessary appliances that go to make up a modern 10-stamp mill. Concretes mortar-blocks, built on solid granite, constitute the battery foundations. All anchor-bolts are so arranged that at any time a broken one may be readily removed, and a new one substituted. A detailed design of the battery is given in this article.

The cyanide annex consists of four pyramidal pulp-thickeners, 7 by 7 by 5 ft., four mechanical agitators with plow-shoes, and vacuum-filters, 10 by 15 ft. diam., four sand-filter clarifying tanks, 6 by 12 ft. diam., six eight-compartment zinc-boxes, and three sumps, 10 by 15 ft. diam. There are three separate pumps, one for aerating, another for vacuum-filtering, and a third for pumping solutions. For the clean-up there is one small acid dissolving-tank. 5 by 3 ft. diam., with hood for disposing of short-zinc, one vacuum-filter precipitate-box. 6 by 7 by 5 ft., and one wash-water settling-tank, 6 by 8 ft. diam. In addition to the above equipment there is a separate room for retorting, melting, and roasting. A small assay and chemical laboratory is also supplied.

The ore on arriving at the mill is weighed, sampled, and dumped onto a grizzly; the undersize passing to the bin, the oversize to the Blake crusher. It is intended that the ore as it is fed to the mortars will pass a 1-in. ring. For crushing and inside-amalgamation we are using a 50-mesh diagonal burr-slot screen. These are of a special 'Duro' steel, and are proving very satisfactory. An 8 to 10-in. discharge, and 8-in. drop, is used at 95 drops per minute. The inside (check and back) copper-plates are 1/4 in. thick. The pulp on discharging from the mortar drops onto a copper splash-plate, and thence onto the lip. From the lip-plate is a drop of 2 in. to the main plate, which is cut in equal sections with 1 1/4-in. drop to each. I find that a 4 by 8 by 10-ft. plate, cut into three equal pieces, is easily taken up and prepared for silver-plating. The splash-lip and outside plates were given a good heavy plating of 2 1/2 to 3 oz. silver per square foot at our plating plant. The 1 1/4-in. drops on the outside plates are the proper thing, for at these plates are the main accumulations of amalgam. These plates when newly plated were 'spongey' (not too compact), and absorbed a large amount of quicksilver at the first dressing. It would take some little time before the plating would cease absorbing the mercury. The deposit was slightly rough and surely was a benefit to amalgamation. A hard compact plating, such as that on tableware, will not absorb nearly the amount of quicksilver, and does not give as good an amalgamating surface. Plates are dressed four times during 24 hr., no cyanide being used. The amalgam on the lower plates is kept at the consistency of putty, while at the splash and lip it is a little harder. 'Quick' is fed every hour to the mortar, the amount being regulated by the richness of the ore. Naturally the lip serves as an indication of what is being done inside, and also acts as a guide to the proper amount of mercury to feed. Both plates are adjustable to grade and we find, with this ore, about 3 to 4 in. to 1 ft. about right. There is a trap at the end of each table. The stamp-duty is 2 1/2 tons per 24 hr. Amalgamation at the present time on this ore gives a saving of 60% inside the mortar, and 15% on the outside plates, a total saving of about 75% of the gold with $20 ore.

The pulp from the plates passes directly to three pulp-thickeners. The clear overflow either flows to waste, or is saved when water is scarce for milling purposes, and the thick underflow passes to an agitator.

The thickened pulp discharges from a 1/2-in. outlet, the pressure-head being 30 in., and the pulp can be diverted to any of the four agitators by a simple slide-adjustment in the launders. At the battery the consistency of the pulp is about 1 to 7, which gives the best results in the pulp-thickeners when a 1 to 3 pulp is required for the agitators. The thickeners are adjusted so as to take about 12 to 14 hr.
to fill one 15-ft. agitator 8 ft. deep. When an agitator is full it contains a charge of about 12 to 15 tons of pulp. While filling, the muller is kept in motion, so as to uniformly distribute the pulp, and if it should be desired to thicken the charge within the agitator so as to make room for a larger charge without stop-

ping the agitator and decanting water, then, while in motion, clear water can be drawn from beneath the filter and run to waste. After the agitator has received a full charge, the agitation is stopped, the muller raised above the settled pulp, and all allowed to settle for 5 hr. However, before stopping the agitator, 8 lb. lime per ton of ore, mixed with hot water, is added to a 12-ton charge and thoroughly stirred for a few minutes. Lime mixed with hot water forms a milk-of-lime, and is very effective for settling purposes. Decantation takes place as soon as the pulp begins to settle, and I find that time is gained by following the pulp down as fast as it settles. It will take longer for a charge to settle if one waits 3 or 4 hr. before starting to decant. Upon completing this operation and at the end of five hours the settled pulp should contain about 40% moisture. Next the muller is lowered and set in motion until the plow-shoes barely scrape the filter, and at this point the muller is clamped, the vacuum applied beneath the filter, and the charge allowed to filter for two hours. When the vacuum-filtering is complete the pulp will contain from 18 to 20% moisture. What little water remains will not dilute the cyanide solutions to any extent. The charge is now ready for cyanide treatment, which occupies 28 hr. out of a total of 48 required to complete the cycle of treatment.

Strong cyanide solution (0.20% free-double cyanides) is next pumped onto the charge until the agitator is nearly full, while at the same time a muller with plow-shoes is being revolved at 18 r. p. m. The muller is lowered so that the points of the shoes barely touch the filter. Every charge receives a 10-hr. agitation and aeration. When aerating, air is forced beneath the filter and bubbles up through the charge. Aeration and agitation are perfect at every point of the vat. After this operation is
finished the agitation is stopped, the air turned off, the muller raised above the settled pulp, and all allowed to settle for a short time. The solutions are sufficiently alkaline, and absorb enough lime from the previous operation to cause the pulp to settle readily, therefore, no lime is added to any of the washes to follow. Next comes the decanting of the strong cyanide-gold solution, which can be done to within 40 to 45% moisture remaining with the settled pulp. Decanting begins as soon as possible after the pulp begins to settle and takes about four hours to complete.

It is not necessary to wait until the solution becomes perfectly clear before decanting, since it is run to sand-clarifying vats and from there flows as clear as crystal to the zinc-boxes. These clarifying-vats also serve as gold-solution storage-vats, so that the flow to the zinc-boxes can be regulated. Within each of these vats is a burlap filter and on top of each is one foot of clean coarse quartz sand. If the solution to be decanted is slightly cloudy all the slime therein will form a thin layer on top of the sand, and is removed with a scoop every three or four days. The slime does not seem to penetrate the sand readily. The pulp remaining within the agitator contains from 40 to 45% moisture in rich gold solution and is next vacuum-filtered down to within 20 to 25% moisture. The agitator is set in motion, and the muller gradually lowered through the pulp until the plows just begin to touch the filter. The shoes revolving next to the filter, prevent any slime-cake from forming, and when the suction is started beneath the filter, the gold-bearing solution is gradually sucked through into the compartment below. Before starting the vacuum the slime, containing 45% moisture, is quite thin and agitates readily, there being no trouble in lowering the muller when the plow-shaped shoes are attached. With a good strong suction beneath the filter the time required to bring the charge down to 25% moisture is about two hours. The pulp with 25% moisture is very thick and sluggish toward the last, but it is possible to filter down to 20%. A total of 6 hr. is required for decantation and vacuum-filtering.

After the removal of the strong solution there follows a 0.10% KCy wash, assaying a trace in gold, which is thoroughly agitated for a few minutes, settled, decanted, and vacuum-filtered. Lastly, a weak barren 0.05% is applied in the same way, and upon the completion of this operation the extraction of the gold-bearing solution is practically complete. The charge is now ready to be run to waste. A little water is added, the discharge-hole opened, and the revolving of the muller will empty the agitator. A final water-wash is not necessary and consequently there are no waste solutions of any apparent value. Both washes have their separate storage and clarifying-vats; they are run through their respective precipitation-boxes to corresponding sumps. I find that with the weak wash, precipitation is very unsatisfactory. If much lime is added for settling purposes, a gray coating on the zinc is formed, and in time this entirely prevents a precipitation of the gold. For this reason no lime is added to the washes.

Sufficient lime for settling purposes seems to be absorbed from the first addition (8 lb. per ton of dry pulp) or what remains with the pulp after extracting the water. This coating is very hard to remove by simply scrubbing the zinc, and I have found an easy way of removing it is to dip the zinc in a very dilute sulphuric acid bath when required.

The cyanide treatment may be summed up as follows:

Probably a short explanation of my combined agitator and vacuum-filter would be proper. All details of construction will be found in the drawings appearing in this article. The muller has four arms at right angles to each other, and to them are attached 26 cast-iron plow-shoes equally spaced. The shoes on opposite arms are arranged to work in between.

The burlap filter is well braced 24 in. from the bottom, and can neither bulge one way nor the other under pressure or vacuum. As a protection to the burlap one-inch boards bored with inch holes are placed on top and well spiked. The filter-cloth is between, and the holes above should coincide with those below in order to get results. The capacity of this 15-ft. agitator is 12 to 15 tons of dry pulp, and it requires about 5 hp. to run it. The heavy pulp, when once in motion at 18 r. p. m., takes very little power. The muller can be easily raised or lowered 2½ ft. An agitator of this type is particularly adapted to the treatment of the total product from the mill-plates, both sand and slime together. There is never any trouble to start or work down a charge after it has settled compactly. With this arrangement a separate vacuum-filter plant is not needed. All the different operations of collecting, agitating, aerating, decanting, and vacuum-filtering are performed in the one vat, and therefore the method requires a plant of the smallest size. The consumption of cyanide is about 1½ lb. per ton with this heavily mineralized ore, keeping the solutions at 0.20% free KCy plus double cyanide, with a protective alkalinity of about 0.5. The plant has now been in successful operation for several months. The mill 'heads' average $20 per ton, the plate tailing $5, and the cyanide tailing about 60c. gold, or a total extraction of 97%. The total cost of treatment is about $1.50 per ton, with the prospect of this being somewhat reduced in the future.
AN ASSAY-PLAN.

Written for the MINING AND SCIENTIFIC PRESS
By L. F. S. Holland.

To those having charge of the operation of metallic ores, mines, readily obtainable and exact information as to the value of the ore, and the daily segregation of costs in all departments, are of first importance. As to the value of the ore, the money received for the products sold will of course show the actual cash value of the ore treated. Few ore deposits are, however, so homogeneous in valuable content that the selection or rejection for mining of parts of the deposit will not considerably affect the ‘profit and loss account.’ To ascertain which ore to select, careful and systematic sectioning and sampling, and the plotting of the results of the assays of the samples are generally essential.

For workings of large extent, such as those on the Smuggler-Union vein, near Teluride, Colorado, which is operated through several miles of levels, an ‘assay plan’ on a scale of even 100 ft. per inch would, on a single sheet, be so large in size, yet so crowded with the plotted assay results, as to be impracticable. The continuous stope-sections on long folding sheets, in use at some of the mines of the Rand, overcome this difficulty in a measure, and are convincing in several respects. In my work in the mines of the Smuggler-Union Mining Co., I have evolved and have had in use for several years a plan that has proved convenient to handle, simple to plot, and able to reveal at a glance the location, value, and width of vein represented by the samples assayed. By means of this plan it is easy to compare one section of the mine with any other. Sheets of good ledger paper of suitable size are filed in a loose-leaf binder, on the principle of the loose-leaf ledgers so much in vogue. The binder can be made with a lock, if desired. When the book lies open, the left-hand leaf has its ‘post’ holes punched in the right-hand margin of the sheet, and the right-hand leaf has holes punched in the left-hand margin. The sheets are ruled and printed on one side only, to suit the particular mine the assay-plan refers to. Movably ‘tabs,’ with clutches slipped over the edges of the leaves, mark the various stopes or levels.

The accompanying diagram shows a portion of a right-hand page of the assay-plan of the Smuggler-Union mine before anything is plotted on the sheet. The leaf is 24 in. long by 12 in. wide. The line at the bottom represents a level, and the proper number of the level is written in front of the word ‘level.’ A line is ruled across the page to correspond with the top of the stope, that is, the level above. In the Smuggler-Union mine the levels vary from 100 to 250 ft. apart.

On this plan, each of the large squares, which are ruled in red ink, represents 50 ft. square on the vein, the scale being 25 ft. per inch. Each of the small squares, which are ruled in faint blue ink, represents 10 ft. square. In mines where stoping ground is figured by the fathom, it is convenient to have these smaller squares represent fathoms.

In the Smuggler-Union mine the ore-ehutes or ‘mills’ are 50 ft. apart, and are numbered consecutively from south to north. These mills are designated on the assay-plan by writing the proper figure in front of the black-face figures at the top and bottom of the page. The figures 10, 20, 30, 40, between the numbers of the mills represent so many feet north of a particular mill. The numbers in the left and right-hand margins represent so many feet up from the level. In this plan each page represents 500 ft. in horizontal distance along the vein, and each opening of the book represents 1000 ft. As the sheets are removable, one section 500 ft. long can be readily compared and correlated with another. For facility of reference it is found advantageous in plotting the assay-results on this particular plan to enter the gold values in red ink, the silver in blue, and the widths, descriptions of vein partings, and other items in black. The location and stopping value of defined ore-shoots can also often be more clearly indicated on the plan by the use of colored inks, assigning a certain stopping-value, or lack of value, to a certain color. In calculating the stopping-value of an ore-shoot, the geometrical mean of the figures, with due allowance for the widths sampled, as well as the assay-values, should of course be taken.

Nickel in ores, even if Co, Fe, or Mn may be present, can be separated by a method devised by Pozzi-Escot, as given below. In a solution of the ore alkali-earth metals are first separated by the use of \( \left( {\text{NH}_4} \right)_2 \text{SO}_4 \) solution. The filtrate is then concentrated, and to it is added a large excess of \( \left( {\text{NH}_4} \right)_2 \text{MoO}_4 \) in saturated solution, and also some \( \text{NiCl}_2 \). This mixture is heated to 80 or 90°C. for some minutes, then stirred frequently for an hour until cold, the cooling being preferably effected by use of ice. All of the Ni is thus precipitated as nickel ammonium molybdate together with most of the iron. Filter, wash with \( \text{NiCl}_2 \) (sat. sol.) and separate Fe by \( \text{NiCl}_2 \) with \( \text{NH}_4\text{OH} \). In the filtrate the Ni can be separated for weighing by any one of many known processes. Grossmann and Sehwek (Bull. Soc. Chim. [4], III., 14) assert that the reaction (which is not new) does not cleanly separate Ni from Co, some insoluble compounds of Co being always formed. Hence it is inapplicable as a test for Ni in Co salts, or in the presence of that element.
THE SILVER VEINS OF THE MONTREAL RIVER DISTRICT, CANADA.

Written for the Mining and Scientific Press
By Alfred Ernest Barlow.

The mineral occurrences in the Montreal River district above Bay lake may be considered as belonging to three distinct areas, namely, the Maple mountain, the James township, and the Bloom lake area. The Maple mountain area consists of a comparatively narrow and irregular intrusion of diabase, occurring to the northwest of Lady Evelyn lake. This mass of diabase extends, with almost unbroken continuity, from the vicinity of Anvil lake northward for nearly nine miles to a point a little east of Boncher lake, near the dividing line between Banks and Speight townships. The outcrops of this diabase vary in width from about a quarter to half a mile, flanked on either side by an arkose, or coarse-grained quartzite, through which it is intruded. The James township area is very much more extensive, including parts of the townships of James, Smyth, Tudhope, Mickle, Farr, and Willett, and embracing what are generally known as the Silver Lake and Hubert Lake districts. The total area in these townships underlaid by the silver-bearing diabase is very nearly 40 square miles. The Bloom lake area is confined to a mass of diabase outcropping in the region to the west of a chain of lakes of which Bloom lake is the largest. The Bloom lake diabase is a mass of irregular outline, with a length of about 10 miles and a width varying from half a mile to nearly 2 miles. The region in the vicinity of James township is much the most important of these mineral areas, for it not only far exceeds the others in extent, but also in the comparative richness of the deposits. At present there are two methods of ingress to the district. The land or winter route commences at Earlton, on the Temiskaming & Northern Ontario railway (26 miles north of Cobalt), and crossing the northern parts of the townships of Armstrong, Beaucamp, Bryce, and Tudhope, reaches Elk lake (Elk City) opposite the mouth of Bear river in the fifth concession of James township. This road is about 30 miles long, 7 miles of which has been already constructed as a wagon road.

Two rival towns, situated on either side of Elk lake (an expansion of the Montreal river), have already sprung into existence, the tents which formed the first residences having now given place to more substantial log structures. Elk City, as the township on the northeast bank of the river has been called, already contains a comfortable hotel and several stores. On the opposite side of the stream, at the mouth of Bear river, the Ontario Government has surveyed a town plot which they have named Smyth.

All of the orebodies in the several mining areas mentioned occur in the form of veins cutting a quartz-diabase or gabbro. Most of the veins in James and surrounding townships occupy two sets of fissures, running approximately north and south and east and west respectively, and therefore nearly at right angles to one another. These fissures are regarded as contraction-cracks formed by the cooling laccolith, which have been filled by later and more acid secretions of the same magma from which the accompanying diabase has solidified. The vein-filling must therefore be regarded as of pegmatitic origin, having the same genetic relationship to diabase that ordinary pegmatite does to granite. For purposes of discussion and correlation, it may therefore be referred to as diabase-pegmatite in preference to the term aplite, by which material in these veins or dikes is now known to the prospectors of the Montreal River district, for the latter would imply the formation of this material as a differentiation product of granite. As a rule these veins are more or less irregular, often curving, sometimes faulted, but surprisingly persistent over long distances. The fissures which they occupy vary from a fraction of an inch, or a mere crack, to 2 ft. or even more in width. Very frequently, too, the same vein may show an equal variation in width both in its horizontal and vertical extension. The narrow veins, especially those from 4 to 8 in. wide, are more commonly met with, and are as a rule more richly charged with the desirable metallic minerals. The wider veins usually contain these either in fairly uniform and continuous, though in comparatively narrow streaks, or in wider and larger, though more or less isolated patches. Many of these veins possess quite sharp and distinct boundaries, the gangue material showing very little if any connection with or transition into the wall-rock. In some instances also the vein along either or both boundaries breaks easily and freely from the accompanying country rock, the orebody in such cases showing quite sharp and regular hanging and foot-walls.

In other and quite frequent cases precisely similar veins show a distinct and, at times, perfect gradation or passage into the surrounding diabase, such a transition being characteristic of either or both walls. Examples are not lacking, especially in the wider occurrences, where there is a pronounced mingling of the material of the vein and the parent phionic rock. In such cases the vein may contain certain vague greenish spots or masses, which have undoubtedly been derived from the diabase, and are now in an altered and disintegrated condition, while the diabase in the more immediate vicinity of the vein is relatively more acid in composition, with abundant quartz, and patches and crystals of the same acid plagioclase characteristic of the vein. Moreover, the minerals, which together make up the diabase, show rather pronounced decomposition due to the same eruptive after-actions as a result of which the accompanying veins have been formed. The plagioclase (labradorite) has been largely converted to a pale yellowish green saussurite, while the original pyroxene has been replaced by an aggregate of chlorite, epidote, and calcite.

The gangue of these veins, in their simplest form of development, shows a fine to moderately coarse-grained feldspathic material, varying in color from a pale pink to deep flesh-red. At first sight most of these veins are remarkable chiefly for the prevailing
absence or scarcity of quartz, although examples are not lacking of veins, evidently very closely related, which contain this mineral as an abundant and occasionally predominant constituent. G. A. Young, of the Geological Survey, made a microscopic examination of this feldspathic material. In the thin sections examined by him, representing several veins from the western part of Tudhope and the central part of James township, by far the largest proportion at least was plagioclase, varying in composition from albite through oligoclase to andesine. This diagnosis was corroborated in part by a separation of the mineral constituents by means of a heavy solution. The plagioclase thus separated varied in specific gravity from 2.609 to 2.653. Some of this plagioclase (albite) had distinct rectangular or lath-like outlines, showing twinning according to both the albite and pericline laws, which in certain cases produced a fine “cross-hatched” structure, usually considered characteristic of the appearance of microcline between crossed nicols. Most of these grains are quite turbid. Another species of plagioclase (oligoclase) occurs in irregular, untwinned, and clear grains, thus resembling quartz; but, unlike quartz, this mineral is readily fusible. Some of these veins contain a considerable admixture of quartz, often forming graphic intergrowths with the feldspars. In certain of these cases, the feldspar has acted as the host, but in others, large grains of quartz were noticed containing only a few shred-like individuals of the plagioclase. Calcite is usually present and sometimes very abundant. This mineral frequently occurs in fairly large grains, or in granular aggregates made up of several individuals, disseminated through the more abundant feldspathic material. It also occurs in more or less continuous vein-like areas or masses, anastomosing between, and sometimes penetrating through, both simple and composite individuals of feldspar. Portions of the vein, where exposed to the action of the weather or percolating waters, frequently present a finely cavernous or sponge-like appearance, due to the etching and removal of the calcite, thereby leaving small and irregular shaped microitic cavities lined with minute tubular crystals of feldspar. Oxidation of the iron sulphides usually present, gives a prevailing pale brownish to an almost black color to these portions of the veins. Not infrequently barite, usually pale pink in color, and occasionally celestite, occur with or replace altogether the calcite and feldspar. Some of these veins are, therefore, made up almost wholly of red feldspar, almost always a plagioclase near the acid end of the series, together with a very subordinate amount of calcite and a still smaller quantity of quartz. Other veins again are made up of an almost equal proportion of plagioclase and calcite and sometimes quartz, while still others present a finer-grained feldspathic portion in the vicinity of the walls, with the whole mass of the interior made up of comparatively coarse-grained calcite, with sometimes a small proportion of quartz. The stages represented completely by the vein occurrences in these districts show a perfect and practically uninterrupted continuity during their con-
solidation from an original condition of hydro-
igneous fusion, characteristic of the magma from which the comparatively fine and even-grained feld-
spathic material is believed to have resulted, to con-
ditions of igneo-aqueous solution which must have obtained in the viscous mass from which the latest calcite or quartzose segregations had solidified.

Chalcopyrite is the most abundant and common of the metallic constituents, but bornite is also fre-
quently met; both of these sulphides often occurring side by side in the same vein. Covellite occurs, but much less frequently. Galena is common and usually carries silver. Many of the veins contain micaeous or specular iron ore and some of them are entirely made up of this material near the surface. Several veins are made up of alternations of chalcopyrite and specular iron ore, while frequently a vein containing specular iron is replaced at a depth sometimes of only a few feet by chalcopyrite, smaltite, and native silver. In the Hubert lake area veins of magnetite have been found, similar to those of hem-
tite in the township of James. Malachite and azur-
ite are common. The cobalt minerals, either smaltite or cobaltite are prevalent, usually in association with more or less niccolite. Erythrite (cobalt bloom) and annabergite (nickel bloom) are also frequently pres-
ent as surface decomposition products. The smaltite-
niccolite veins often contain the white bloom near the surface, which is formed by the reactions of these minerals upon one another when subject to weathering processes. Most of these veins will give assay values in silver from a fraction of an ounce to 30 oz., or even more, per ton, although the material on which the trials were conducted showed no signs of the native metal. Silver is of common occurrence in these veins, both in the native state and as argentite (sulphide of silver). As native silver it occurs in nuggets of various shapes and sizes, as well as in fine flakes and scales disseminated through any of the various gangue minerals, feld-
spar, calcite, barite, or quartz. Beautiful fern-like skeleton crystals of native silver are frequently found in certain cavities in these veins from which the enclosing calcite has been removed as a result of weathering. The mode of occurrence and asso-
ciaction of the silver in some of these veins bears a striking resemblance to that obtaining in the veins cutting the diabase in the vicinity of Kerr lake near Cobalt. All of these veins occur in diabase or gab-
bro, a rock which represents the consolidation of a lava of basie composition, which has been intruded in the form of sills or laccoliths and dikes through rocks of Huronian, Keewatin, and Laurentian ages. The rocks representative of the Huronian are con-
glomerates, slates, and arkoses or quartzites, similar in structure and mineralogical composition to rocks of the same geological age found in the neighborhood of Cobalt. No rocks of Keewatin age have been found in James township, but extensive outcrops occur in the central and eastern portions of Tudhope township. The Keewatin is intruded by certain granites and gneisses which are usually referred to as Laurentian. These two rocks form an igneous complex lying unconformably beneath and furnish-
ing pebbles and other detrital material of which the basal conglomerates of the Lower Huronian are composed. The diabase or silver-bearing formation is the newest rock in the district, as it is intruded through all the other series, cutting even the arkoses and quartzites, which are at the summit of the sedimentaries. All of the veins of economic importance so far discovered appear to be confined to this diabase, which is essentially similar in mineralogical composition and geological age to that in which occur some of the most productive silver veins of the Cobalt district.

The hand specimens usually show a dark green, more rarely grayish, medium or coarse-grained rock, made up of irregular prisms or grains of a dark green mineral and a dull, light greenish feldspar, showing only an occasional cleavage-face. One of the least altered of these specimens was obtained from the Miller location in the western part of Tuedhope. Under the microscope the rock proved to be a rather coarse diabase, considerably altered, but with its typical mineralogical composition and structure still distinct. Originally it appears to have been composed of nearly colorless pyroxene, occurring in large and small often twinned, but shapeless plates penetrated by laths of plagioclase. These individuals of feldspar are twinned according to the albite law, unaccompanied by carlsbad twinning or zonal structures. They vary greatly in size, the inter-spaces being filled with irregular grains of quartz, which mineral forms no small proportion of the rock. A few flakes of deep brown, highly pleochroic biotite are also present. Much of the feldspar, often in the central part of the individuals, is completely altered, apparently to epidote, while the pyroxene is associated with secondary minerals including a pale-green somewhat fibrous hornblende. The rock shows no abnormal characters and may be described as a somewhat decomposed quartz-diabase. Another specimen from a claim in the northwest corner of Tuedhope appeared to represent a diabase, although the original pyroxene has been completely removed. The part of the rock represented by the slide is largely composed of tabular individuals of plagioclase sharply idiomorphic and with much interstitial quartz. The plagioclase shows prominent albite twinning, sometimes accompanied by carlsbad twinning, and in two such cases the values of the extinction angles indicated an acid labradorite. The interstitial quartz in many instances almost seemed to be replacing the feldspar, isolated shreds of which sometimes lie in the quartz or form skeleton-like aggregates similarly orientated. Occasionally the relations are reversed, and the feldspar then includes a number of separate grains of quartz in optical continuity with one another. No evidence was afforded that the quartz was of more than one generation; and because of the general occurrence of this mineral in the unaltered diabase of the district it was concluded that the quartz was original. Besides this feldspar and quartz, calcite and chlorite compose a considerable proportion of the section. The chlorite occurs in small aggregates between, or distributed through, the feldspar. The calcite forms plates and granular aggregates. Both these minerals appear to replace the original pyroxene.

To summarize the conclusions, then, the diabase of the Maple mountains, James township, and Bloom lake areas is essentially and prevailingly a quartz-diabase. In many instances this quartz occurs as a granophyric or graphic intergrowth with the plagioclase, which is usually an acid labradorite. The presence and usual abundance of this original or primary quartz marks the rock as a rather exceptional type and district from ordinary diabase, which as a rule contains little or none of this mineral. Diabase and similar basic igneous rocks have been artificially reproduced in the laboratory from a state of simply dry fusion: but it is extremely doubtful whether any extensive intrusive process produced by natural causes is ever unaccompanied by a greater or less abundance of superheated water as an integral portion of the fused mass. This condition of dry fusion, however, is distinctly approached in a magma from which an ordinary diabase has been formed. During the intrusion and subsequent solidification of the diabase described in the present paper, however, there has been a very general superabundance of these heated waters and vapors, which not only accompanied the crystallization of the great mass of the ordinary parent plintron, but were especially present and active in the formation of the pegmatitic mineral veins which represent the expiring efforts of this intrusion. The presence of the abundant original quartz, often in graphic intergrowth with the plagioclase and the breaking down and replacement of the original pyroxene by chlorite and calcite, is distinct evidence of the presence of superheated waters and steam present in and traversing the ordinary or finer-grained phases of the diabase.

The rock is, therefore, more highly quartzose than usual, which fact accounts in the main for the presence of the associated mineral-bearing veins. The presence of these veins in the several mining districts mentioned is due primarily to a profound fissuring of the diabase itself, formed probably as a result of the contraction of the rock in cooling, the resultant cracks and cavities being occupied in many cases as fast as they were formed by the later, more acid, and hydrated segregations from the same diabase magma. The veins in their simplest forms of development are, therefore, essentially of pegmatitic type, although some of the more complex types and those at the other extreme made up almost wholly of calcite or quartz show little or no evidence of such an origin. The various stages in the formation of these veins are completely represented in these mining areas, showing a perfect and practically uninterrupted continuity during their formation from an original condition of hydro-igneous fusion characteristic of the magma from which the comparatively fine and even-grained feldspathic material is believed to have resulted, to conditions of igneous solutions which must have obtained in the viscous mass from which the latest calcite and quartzose segregations have solidified. The feldspar in this diabase-pegmatite is essentially a plagioclase near the acid end of the series, chiefly albite and
oligoclase, but sometimes andesine, in contradistinction to ordinary or granite-pegmatite which contains orthoclase, microcline, and microperthite as the predominant and characteristic feldspar. Quartz is not essential and some of the more representative types of this diabase-pegmatite in these veins contain less than 5% of this mineral. Calcite is almost invariably present, and in extreme phases, or those which have been formed as a result of pronounced secondary action, completely replaces the feldspar.

The age relations of the mineral constituents of the gangue are fairly simple, although the several minerals constantly overlap in their periods of gen-

SMELTING WORKS AT RIO BLANCO, PERU.

Written for the MINING AND SCIENTIFIC PRESS
By An Occasional Contributor.

The smelter of the Peruvian Mining, Smelting & Refining Co., which has just been blown in at Rio Blanco, Peru, is the second great enterprise inaugurated under American auspices, with American capital, in that country. It has begun its career with a first-class installation, under the best engineering advice, and is conducted under the management of men of high training and experience. The Company was organized in the United States by A. F. Holden, E. A. Clark, W. H. Coolidge, L. Vogelstein, E. A. Wiltsee, and J. L. East, and incorporated under the laws of the State of Maine on July 16, 1906, with a capital of $5,000,000 gold, the object being to exploit mines in Peru and to build a smelter, which has but recently been completed. The Company’s main office is in Boston, its president being A. S. Hight and its treasurer S. E. Farwell. The Peruvian representative is J. L. East, who is general manager, with S. C. Hazleton as smelter superintendent, M. F. Church as constructing engineer, G. Wagner as mine superintendent, and A. A. Abbott as consulting engineer.

The plant is situated in Rio Blanco and, as shown in the accompanying illustration, is in a deep gorge in the Andes. A comparatively level bottom affords an ample site for the works. The mountain walls

Copper Smelting Works, Rio Blanco, Peru.
are almost precipitous on every side, but are nevertheless covered in many places by terraced gardens to a great height above the river.

The Ferrocarril Central del Peru gives communication with the port of Callao, as well as with the capital of the Republic, the respective distances being 135 and 120 kilometres. The same line also connects the smelter with the mining district of Yauli, which is 50 kilometres distant, where are the chief mines of the Company. By the same road connection is made with Cerro de Pasco.

The mines of Churruces, which are situated at the end of the railroad, are prepared to produce 200 tons of copper-ore daily, averaging 9%, with considerable silver and gold content. In order to be able to work to its full capacity the Company has bought the necessary ores in the districts of Yauli and Morococha, which are among the most important in the country. For this purpose it has signed contracts with the owners of the Gertrudis, Alapampa, Ana- canapa, Austria Duvas, and other mines, which can furnish a greater quantity of ore than is required by the capacity of the smelter. Ore can also be purchased in the district of Cerro de Pasco.

The smelting plant of the Peruvian Mining, Smelting & Refining Co. is designed to treat 300 tons of ore per day, producing a matte ranging from 50 to 60% copper, which is planned to ship abroad for refining. Though the initial capacity of the plant is limited to one blast-furnace already constructed, all necessary installations have been designed for fully double the tonnage, and provision has been made for the erection of a second furnace. The capacity of the plant can accordingly be increased to 600 tons per day as soon as conditions warrant, with but little delay. The blast-furnace is water-jacketed, and measures 44 by 186 in. at the tuyeres. It is housed in a steel building, the latter of double the necessary size, so as to provide for a second furnace. The flue for leading off the waste gases is situated behind the blast-furnace building. It is of brick construction, carried on steel columns, the bottom being hoppers for automatic discharge of the accumulated dust. Two large dust-settling chambers, built of masonry, intervene between the flue and the stack. The latter is of steel, 150 ft. high and 12 ft. diam. Directly beyond the flue on the feed-level are the ore, flux, and coke-bins, and the 'sintering plant.' The ore-bins have a capacity for 12,000 tons, and storage is provided for 600 tons of limestone and 300 tons of coke. The 'sintering plant' is designed for sintering fine ores so as to put them in a better physical condition for the blast-furnace, and consists of 12 pots of about 1-ton capacity each. It is estimated that 100 tons per day will be treated in these pots. Back of the ore-bins, on a level with their tops, are situated the assay office and sampling mill. The latter is equipped with Vezin automatic sampling machinery, and will handle 60 tons per hour. The main line of the Ferrocarril Central del Peru passes behind and above the sampling mill, and a spur-track therefrom, running on a trestle, serves for the receipt and unloading of cars of ore. Beneath the trestle are ore-bins for receiving the ore in the first instance. These discharge on a conveyor belt, which carries the ore to the sampling mill. From the latter the ore is distributed to the ore-storage bins and thence to the furnace. It will be noted that gravity assists in the handling throughout.

The power for operating the plant is derived from the Rio Blanco river. A pipe-line 40 in. diam. and about 1200 ft. long delivers the water to the powerhouse under an effective head of 120 ft. This gives approximately 500 hp. The installation of the powerhouse consists of three 35-kw. direct-current generators and one Root blower of 20,000 cu. ft. per minute capacity, all driven by Pelton water-wheels. The generators furnish electric current for lighting purposes, and for the motors used at the several points around the plant for driving machinery. A machine shop and blacksmith shop, office building, and dwellings for employees complete the installation.

A new reducer in fire assaying is described by C. A. Rose in The Mining World. It is quite well known that much annoyance is experienced in assaying highly silicious ores by reason of the contents of the crucible boiling over when argol or other carbonaceous reducing agents are used, and to avoid this it is necessary to start the fusion at a low temperature and heat gradually, although a crucible is not so liable to boil over if the fusion is started in a very hot muffle. Sometimes a cover of salt is used to prevent this boiling, but in that case the fume is troublesome in pouring, if the slag is decanted from the lead. This boiling is caused by the disengagement of carbon dioxide from the carbon in the reducing agent. If a fusion is made without a reducing agent it will not boil over. If a sulphide were used as a reducing agent no gas whatever would be produced from this source, since the metal would combine with the silica and the sulphur would be converted to sodium sulphate. This would have the double advantage of producing more quiet fusion and introducing a basic element into the slag. Probably the most convenient sulphide for this purpose is iron sulphide, which can be obtained free from gold and silver. This was tried with satisfactory results. Silicious ores that boiled badly when a 0.5 assay ton was fused in a 20-gm. crucible, using argol as a reducing agent, gave no trouble whatever when the assay was made in a 15-gm. crucible, with the same quantity of ore and iron sulphide used in the place of argol. According to the equation,

\[ \text{FeS} + 4\text{PbO} = 4\text{Pb} + \text{FeO} + \text{SO}_2 \]

1 gm. of iron sulphide ought to reduce 9.4 gm. of lead. In practice about 9 gm. are obtained, so that the reaction is nearly quantitative. The following charge was used: 0.5 assay ton of ore: 80 gm. litharge, 20 gm. sodium bicarbonate, 10 gm. potassium carbonate, 3 gm. iron sulphide. The use of iron sulphide as a reducing agent is new, and it ought to appeal to those having sulphide ores to assay by the nitre method. Its use instead of argol saves about 15 to 20 minutes in time of fusion.
AIR-DRILLS AND THEIR EFFICIENCY.

Written for the MINING AND SCIENTIFIC PRESS
By SAMUEL K. PATTERSON.

Probably no branch of engineering development is on a par today with that of air-drill operation from the standpoint of inadequate efficiency. The introduction of the air-drill in mining and as an industrial factor for other purposes was a great step in advance and represented considerable progress in engineering development, but since that time air-drills themselves have made little or no progress in efficiency. Many of the ordinary facts or physical data essential for their operation are practically unknown, and this is due as much to the lack of adequate methods for their determination as to any other reason. Thus, even the question of what is meant by efficiency of an air-drill is debatable ground. The average manufacturer will say that it depends upon the initial air-pressure, air-consumption, and rate of drilling, but that no adequate or scientific conception of the same is possible or at hand. It is a generally accepted theory that air-drills in actual operation work best with an air-pressure of 80 to 100 lb. Some extend this to 150 lb. initial pressure. The air-consumption varies with the size of the drill, but for the average drill it is approximately 100 to 150 cu. ft. of free air per minute, compressed to 80 or 100 lb., taking the full supply available from an average 8 by 8-in. compressor. Until recently the speed of such drills, or the number of blows per minute, was variable and practically unknown, and the foot-pounds of the blow has been determined in rare instances only. No indicator diagram of the action in the cylinder has ever been made or is obtainable with the ordinary indicator on account of the inadequacy of this mechanism for such speeds, and because of the high corrective factor due to inertia and to the velocity of its parts. The action of the valves, and the effect of the port in reducing the air-pressure, are largely a matter of conjecture.

All drills for mining purposes can be divided essentially into two classes, those in which the valves operate by mechanical means imparted by the motion of the piston itself, and those operated by a differential air-pressure produced in various ways. The position of the valve is apparently determined largely by question of convenience in design from an operative and constructive viewpoint, rather than from the view of efficiency or air-consumption. The Ingersoll-Rand pneumatic hammers and drills have a valve operating by differential air-pressure at right angles to the motion of the piston, and installed in the handle of the device or at one end of the piston-cylinder. This necessitates comparatively long ports for the action of the hammer or drill during a portion of its stroke. The Rix pneumatic air-drill possesses a mechanically operated valve installed in a cylinder parallel to that of the piston proper, and possesses much wider ports and equally distributed passages. The McKiernan drill possesses features of both types, with a side valve-chamber operated by differential air-pressure. Other types are more or less similar, and the data herein given refers more especially to the average drill used in mining. Air-driven hammers, saws, augers, riveting machines, and a number of other devices, fall equally in this category, but their range is so wide, and their variability so great, that they have not been considered. However, all the conditions which hold in this particular type hold equally well in regard to the majority of air-driven tools where the frequency of the device operated is of such a character as to preclude the utilization of the ordinary appliances in their measurement.

The ordinary steam indicators as used in the indication of steam units, pumping machinery, ammonia and air-compressors, are inadequate as instruments of precision in this particular field. In fact, no satisfactory indicator for high-speed gas-engines is as yet available. Equal conditions hold in regard to high-speed steam engines, especially those direct-connected to electric generating units, and the necessity for a satisfactory indicating device where the problems of inertia and rigidity have been satisfactorily met for these speeds will undoubtedly prove as great a boon in the utilization of compressed-air as in the production of power by any kind of the high-speed engines. In regard to the action of compressed air in an air-drill it is assumed to be somewhat similar to that of steam in reciprocating-pump machinery. No cut-off exists in either type, and the pressure is supposed to be maintained more or less constant throughout the stroke. However, the use of indicators or pressure-gauges direct-connected to the cylinder of air-drills registers a fall in pressure of from 20 to 40% over that existing in the hose and valve-chamber, and whether this is due to inadequate size of ports or is in reality a measure of the average or mean effective-pressure is unknown. Only recently has this drop in pressure in the air-cylinder of the drill become generally known, and a more thorough study of the phenomenon is being undertaken.

Again it has been the generally accepted dictum among air-drill operators and superintendents that air-drills operate at a maximum efficiency of from 80 to 150 lb. air-pressure. That such drills should operate more efficiently at higher pressures is a reasonable conclusion if faults of design do not enter. It is also reasonable to assume, within certain limits, that a given drill should possess a maximum efficiency at a given initial air-pressure, due equally to details of design and operation. However, the statement that all air-drills are limited in their maximum efficiency, independent of design, to certain values in initial air-pressure is, if correct, undoubtedly due to faults in the design and operation of such types. The use of differential air-pressure in the operation of the valve, with this differential air-pressure obtained by allowing the direct ejection of a portion of the air into the atmosphere through an intermediate air-chamber at one end of the valve-piston, is not only an extremely wasteful device for the operation of the piston, but is an unnecessary one as well. It has also been the generally accepted conception of engineers that all drills other than compressed-air...
drills have been tried and proved unsatisfactory. While undoubtedly this may be true under present conditions, that it is a necessary condition is by no means a foregone conclusion. The type of drill in which the air is compressed by electrical means in the immediate vicinity of the air-cylinder, to be used at once, represents a possible development along lines possessing considerable advantages. The condition of affairs may be summed up in the statement that our knowledge of operating conditions in the utilization of compressed air in the average air-drill, and in other air-drills, is essentially inadequate, and more complete information is highly desirable.

The average air-drill makes from 400 to 1000 blows per minute with an air-pressure varying from 50 to 100 lb. With increased air-pressure the number of blows per minute could undoubtedly be considerably increased, but such a result could be accomplished only by a change in the valve-device, utilizing the motion of the piston. The question of ports, their size and length, is a matter of vital importance in the operation of such drills, and the possibility of a suitable cut-off, with the object of diminishing air-consumption, is equally important. Again, the question of utilizing heat for re-heaters, with the object of diminishing the air-density and consequent air-consumption, has not been met in more than a tentative manner. Steam can be used in such types of drills in place of air, but is unsatisfactory for a number of reasons, and the utilization of air and steam combined is a question which is in an experimental stage of development.

Mechanical efficiency, however, is in reality a matter of minor significance in the operation of air-drills in comparison to that involved in a consideration of the factors affecting the commercial efficiency. Thus, the labor cost and other items are such in the operation of air-drills that the efficiency of a drill is measured in reality by the time of boring, and is practically independent of air-consumption in the choice of a type. The drill which has a small percentage-increase in the rate of digging can in reality consume several times the quantity of air in its operation and still be more efficient, on the commercial side, than the more efficient mechanical type in the actual operation of the drill itself.

A CONCRETE-BLOCK CHIMNEY.

A novel system of chimney construction, the invention of M. Dumas, of Brussels, is described in Engineering News of August 20. It has been covered by patents and is controlled by the firm of Léon Monnoyer et Fils, contractors, of Brussels. While the chimney is constructed of concrete blocks, reinforcement is used with it, and there would appear to be no difficulty in proportioning this reinforcement to the stresses to be sustained. It may be noted, also, that the vertical reinforcing rods are so placed as to be much less exposed to the interior heat than is ordinarily the case. The blocks are of large size, permitting rapid construction, and the provision for securing the taper in the chimney construction is particularly ingenious. The chimney is polygonal in cross-section, and may be built with 8, 10, 12, or more sides, according to the size of the structure. The casting of the concrete blocks is illustrated in Fig. 1, which shows a cross-section of the block in the mold. As seen in the drawing, the cast-iron sides of the mold are in three pieces only, and the ends of the mold are formed by wooden stop-blocks. By adjusting the position of these stop-blocks, the length of the concrete block can be altered to suit the course in which it is placed; thus the taper of the chimney is secured without multi-

Fig. 1.

Fig. 2.

blocks are molded a wooden strip of triangular cross-section. This leaves a V-shaped groove in the block, in which a rod or wire may be placed for reinforcement. The blocks are usually about 10 in. high and the thickness varies from 6 in. for the bottom courses of the chimney to about 3 in. near the top. Rods are molded in the blocks for convenience in handling them. The large size of the blocks, and the fact that they are erected without scaffolding, enables the chimney to be constructed with a small working-force and with great rapidity. It is claimed also that the cost of these chimneys is less than that of chimneys made in any other way.

An alloy of aluminum and magnesium called magnesium is said to have greater strength than aluminum, inspite of being lighter, its specific gravity being about 2.5, while that of pure aluminum is 2.64. It can be forged like Swedish steel and worked like brass, giving a smooth surface of silvery color. It attains and maintains a high polish, and is unaffected by atmospheric agents. Magnesium can be soldered; its electric conductivity is 56% that of pure copper; its melting point is 1185 to 1250°F.; its specific heat is 0.2185.
Mine Reports.

WAHINE GOLD MINING CO., NEW ZEALAND.

The report for the year ending December 31, 1907, states that 356,974 tons of ore yielded £578,185 15s. 16d., the gross revenue being £884,538 18s. 16d. The expenditure in New Zealand and London amounted to £572,974 8s. 5d., leaving a profit of £591,910 15s. 2d., as against £592,673 in 1906. The four dividends absorbed £322,339 11s., as compared to £297,541 in 1906. A further bonus of 8s. per share, declared at the annual meeting, makes the total distribution 16s. per share, or 50% on the capital for the year.

In the mine the ore reserves are estimated to be 1,299,979 short tons, as against 1,629,653 twelve months earlier. The deepest shaft has reached 1620 ft. The ore comes from no less than 14 so-called 'reefs' or lodes. On the eighth level the orebodies have proved to be of great width, ranging from 50 to 92 ft., and in places as much as 75 ft. of the quartz assays over £10 per ton in gold and silver.

During 1907 the stamp-mills treated 28,188 more tons than in 1906. Seven tube-mills are in use. The gas plant proved a successful economy as against steam. The yield from the ore was £2 14s. 11d., as against £2 17s. 8d. in the previous year, but the working expenses were less. The mills are three in number and contain 90, 200, and 40 stamps, respectively. The duty is £3,794 tons per stamp; 5631 tons of concentrate yielded £140,480. Of the total yield of 1,332,621 oz., no less than 559,362 oz. came from the three mills and 373,259 oz. from the plant treating concentrate. Up to the end of 1907 this mine had yielded profits amounting to £2,571,327 on its capital of £500,000, in 15 years.

BROKEN HILL PROPRIETARY, NEW SOUTH WALES.

The 16th half-yearly report for the six months ending on May 31, 1908, states that the gross profit amounts to £36,588 and the net profit £23,776, as against £37,642 for the previous half-year. The profit was 1s. 8d. per ton of ore, and £2 9d. per ton, during the preceding six months. Only one dividend (amounting to £32,600) was distributed during the period under review. The output of the mine was 273,557 tons, the nine furnaces at Port Pirie smelted 169,482 tons of ore and slime, besides by-products, making the total smelted 312,068 tons.

The financial results reflect the condition of the metal market, rather than that of the mine. Silver, which on November 30, 1907, was at 2s. 2½d. per ounce, stood at 2s. 6d. on July 16d., at the close of the half-year; and during the same period lead receded from £15 18s. 9d. to £13 per ton. The deepest workings in the mine are at 1400 ft., and on that level the orebody is from 6 to 44 ft. wide. This ore assays 20% lead, 16% zinc, and 14% silver per ton.

Improved Copper Converters.

BY HERBERT HAAS.

The Union Iron Works Co. has recently designed new types of copper converters, which combine all the progressive improvements made in late years at the different copper reduction works in this country. One type is electrically operated and the other is a converter tilted by hydraulic pressure. These converters embody the following novel features of construction: The shells are of sheet-steel, and to permit of securing the lining, the parting joint between the bottom and top portions is placed considerably above the centre, and both sides extend from the centre-line straight upward and slightly inward, at an angle of approximately 6° 45', with a tangent normal to the centre-line. With this construction, the life of the lining is greatly increased, as the lining can be secured better than in the old converters, where the shell was parted in two halves and the sides of the upper portion were curved to the radius of the converter-shell. Rapid corrosion of this joint by the matte, a common defect in the old type of converter, is retarded by placing the joint of the two halves high above the centre-line. The shells are riveted to spherical heads made of best open-hearth Bethlehem casting steel, and are reinforced with heavy ribs. This form of head was designed to withstand the heavy stresses due to expansion and contraction produced by the high degree of heat, and to give the magnetic bricks or chromite blocks a good hold. These refractory liners are usually placed nearest the shells to prevent burning of the shells, should the silicious lining become completely eaten away through too prolonged blowing. The flanges of the heads form the riding-rings, which are of a diameter to permit of a complete revolution of the converter.

The bottom and top halves have heavy cast-steel angles riveted near the joint, which reinforce the shells and serve to connect the two halves, these being held together on each side by three large copper-bolts. Cast integral with the steel angles, there is at each end of each plate a lifting lug, or eight lugs in all, the four lower lugs serving to lift the entire shell from its stand, the four upper lugs to lift the top from the shell.

Notable features are the construction of the wind-box independent of the tuyeres, and the provision of individual tuyeres. The tuyere-box is supported by angles riveted to the shell and does not come in direct contact with the shell, and air-space being left between the shell and the box, thereby reducing the expansion and contraction, and increasing the life of the wind-box. To the flanged portion of the box, which has as many openings as there are tuyeres, the individual tuyeres, made of casting-steel, are se-
by cuts that truly illustrate, detail drawings being abundant for the elucidation of the text. The topics treated are, in part, structure and operation of compressors, theory of air-compression, wet and dry compressors, compounding, three chapters on values, duty, regulation, receivers, reduction for altitude, explosions, and finally, an excellent discussion of air-compression by the direct action of falling water, with descriptions and detailed illustrations of the famous Magog and Victoria plants. Part second discusses transmission in great detail, difficulties and advantages of utilizing compressed air as a motive fluid in engines and pumps, re-heating, haulage by compressed air, and a general explanation of efficiency of air-drills. The book is amply supplied with explanations, formulae and tables for the designing of air-motors and air-driven compressors and compressed-air application. It is a book which will be greatly appreciated as a guide and assistant to mine managers, engineers, and students. It is the best 'round-up' of the subject we have seen.

Commercial Paragraphs.

AHLIS-CHALMERS Co., Milwaukee, is prepared to send its Bulletin No. 1431 to anyone interested in the operation of Huntington mills.

THE RIX Compressed AIR & DRILL Co., San Francisco, announces that hereafter its office and salesroom will be at 371 Market street, and the factory at 219 Spear street.

David Goodeal has retired as manager of the Compania Minera Rio Tinto Mexican, at Terrenas, Chih., Mexico, and will open an office for practical practice at Berkeley, California.

The G. T. Ingerson Machinery Co., Salt Lake, has recently put in two special Byron Jackson turbine pumps at the mill of the Boston Consolidated, on the shores of the Great Salt Lake. The static head under which the pumps work is 250 feet.

The NATIONAL BATTERY Co., Buffalo, N. Y., announces that the receivership under which that Company has been operating since last February, was terminated August 19. The control of the re-organized Company rests with The Cutler Hammer Mfg. Co., of Milwaukee.

The Dixon Iron Works, San Francisco, received word last week that the gold dredge manufactured by them for the Nome, Montana & New Mexico Mining Co started operation August 25. This dredge was erected in 50 days, which, considering the difficulties encountered in the Far North, is quite a record.

The DEUTER CONCENTRATOR Co., Fort Wayne, Ind., advises that it has recently received orders for Deister tables as follows: Four tables for the Conimex Mining Co., Mexico; eight for the Cia. Minera Och racially, Toluca, Mexico; four for the Granby Mining & Smelting Co., Joplin, Mo.; and one for the Buffalo Mines Co., Cobalt, Canada.

The Wood DRILL Works, of Paterson, N. J., is distributing through its Mexican office, the International Machinery & Engineering Co., Edificio de la Munta, Mexico, D. F., a 12-page booklet, neatly bound, entitled 'The Improved Wood Rock Drill,' giving a brief description of the Company's objects, some valuable information to drill purchasers, and some facts on the great Zuni dam, in New Mexico.

Catalogues Received.

The NATIONAL ORE CONCENTRATION Co., Chicago, has recently published Bulletin No. 5, descriptive of the Woodbury system of concentration.

The U. S. FLEXIBLE METALLIC TUBE Co., of Los Angeles and San Francisco, announces a new illustrated price list, which will be sent to those interested in connection.

The FOOS GAS ENGINE Co., Springfield, Ohio, has lately issued Circular No. 77, which is a well printed booklet giving particulars concerning gasoline hoists, a new type recently added to its line of horizontal and vertical engines.
WHILE THE REVIVAL in the shares of South African mining companies is of particular interest to London and Berlin, it is welcomed also in New York and San Francisco, for the recent rise in Kaffir shares indicates the re-awakening of interest in mining the world over. The depression in South Africa has been a wet blanket upon the international mining market, and we are glad to see signs of returning cheerfulness.

ON SEPTEMBER 19, and several days thereafter, the region around Nome suffered from an early and severe frost, which compelled a complete cessation of hydraulic mining and necessitated the diversion of water from the ditches. A heavy fall of snow followed, covering the ground to a depth of from two to six inches. We hope to hear that this did not mark the end of the operating season, but it looks discouraging. Locally, the occurrence would be termed "a dry freeze-up."

FROM A PROFESSIONAL point of view, we should be loath to accept the statement of Mr. James L. Calbreath, made before the Trans-Mississippi Congress, that "75 per cent of the best brains in the metallurgical world" is controlled today by the American Smelting & Refining Company. The aggregation of talent retained by that corporation is not as impressive today as it has been in the past, although it still includes some of the cleverest men engaged in fire metallurgy, but at no time, we are glad to say, did the smelter trust approach to within 25 per cent of a monopoly upon the best available talent in America.

OUR CORRESPONDENT at Kalgoorlie refers to an interesting case for breach of contract brought by Mr. E. S. King against the Ivanhoe Gold Corporation. It appears that a number of men, even with A. R. S. M. after their names, denied to Mr. King the status of a fully fledged metallurgist and decribed the value of his services. Our sympathy is wholly with the man who "does things," whether his name has a luminous tail or not, and we are glad that Mr. King was able to enforce payment for services rendered. We have read in a book about brothers-in-law who did not agree as to what was honorable, and here also we venture to congratulate Mr. King on the verdict of the court.

BRIGHT is a beautifully situated little town in the Australian Alps. It has a race-course; the trustees of that race-course have given a syndicate the right to dredge the area comprised within its boundaries. It is a pity other race-courses are not gold-bearing in a natural way; unfortunately the
profitable character of them is dependent upon chicanery and fraud. Next let us put the race-track men to useful employment, and though they would be unfitted as a crew on a drudge, they might serve for those sad-sounding but necessary anchorages called ‘dead-men.’ We shall send a marked copy to Governor Hughes of New York.

IN ORDER TO ENCOURAGE investigation, a committee has been formed at Johannesburg for the purpose of considering proposals that have for their object the more economical extraction of gold from ore. It is stipulated that ‘any suggestion which the applicant considers patentable must be provisionally protected by him before being submitted to the Committee.’ This seems likely to defeat the whole purpose in view; if the Committee desire to prevent the overlap of inventive talent, it is their first duty to protect those who are contributing tentative ideas.

ROMANTIC as is the history of mining on the Comstock, it is safe to say that nowhere has the extraction of wealth from the ground on a large scale been accompanied by so much petty scheming and sordid chicanery. On another page Mr. Whitman Symmes, a trustworthy investigator, testifies to the rotten methods of the handful of brokers who have preyed for so many years upon the decadent energies of Virginia City and Gold Hill. It is not pleasant reading, and it would be no pleasure to devote our pages to the recital of the story, save for the hope that exposure may lead to reform. The history of Comstock mining proves the credulity of the public when dazzled by the records of past production, and the defenseless condition of scattered shareholders.

OUR CONTEMPORARY, the Electrochemical and Metallurgical Industry, makes frequent comment on professional matters in a thoughtful sympathetic manner, reflecting the wide culture of its accomplished editor. In the last issue kindly reference is made to the acceptance of a professorship by a successful metallurgist as evincing a professional altruism distinctly rare. We venture to add our own approval to the action of a friend, to emphasize the philosophic good sense of a college graduate sufficiently educated to know that man does not live by bread alone, that the shekels of the financier are not completely sustaining to the life of a broad-gauge man, that the accumulation of money beyond the necessities of cleanliness and comfort is a dreary business, and, finally, that to teach the young dynamic men of the country to be efficient is a task of patriotism, worthy of the best American citizen.

CALIFORNIA has lost some of her former prominence as a region for hydraulic mining, because the debris legislation put a stop to the big operations in the watersheds of the Sacramento and San Joaquin rivers. Hence, it is sometimes forgotten that hydraulic mining flourishes in the northern part of the State, especially in the region drained by the Trinity and Klamath rivers, where the obstructive farmer has been unable to place a benumbing hand upon the mining industry. Of the mines of this class in northern California, the most important is the La Grange, a historic enterprise, the details of which are related in this issue by Mr. Donald F. Campbell. While hydraulic mining has declined in importance along the foothill districts of the Sierra Nevada, the men who obtained their training in California are now playing a useful part in the development of the North; they are contributing their assistance to the exploration of the rich alluvium of the Yukon and Alaska.

Discussion.

THE DEPARTMENT of this journal devoted to discussion is growing in importance and we are glad to note the development, for there is good reason to believe that the ‘letters to the editor’ serve an excellent purpose. Apart from the information afforded by many of them, such communications from our readers are useful in checking any extravagance of opinion or any violent prejudices on the part of the editor. It is well to have a subject discussed from many points of view, and it is sanitary to feel that a correction is possible from the outside. Assuredly the editors of this journal welcome the free expression of opinion on the part of their readers, as tending to a sane balance and as conducive to an increased interest in the pages of this periodical publication. The Discussion department has proved useful in eliciting special information; it serves as a clearing house of ideas and experience. Occasionally a letter is signed with initials or a nom de guerre. In such cases the identity of the writer is known to the Editor, for no really anonymous communication is ever accepted. As a matter of good faith, every contributor must declare himself, even though his name be not published. Undoubtedly ‘letters to the editor’ must be bona-fide expressions of independent opinion, and when a member of the editorial staff chooses to step down, as it were, from the pulpit and speak from among the congregation, he must do so without masquerading under an assumed name. The ‘letters to the editor’ are the comments of the reader in response to the comment of the editor, and when occasionally an editor wishes to speak as an individual observer or as a specialist in a particular subject, he may find it simpler to place himself among the readers. At least that is our practice, for our editors have been so recently engaged as engineers and geologists that they like once in a while to get into the mélée of a controversy rather than pose as judges detached from the fun of conflict. Recently The Times lost a libel suit to Mr. John Murray, the publisher. It was proved that a letter to the editor signed ‘Artifex’ was written at the suggestion of the manager of The Times book department and was not the expression of opinion volunteered by an independent person. The letter attacked Mr. Murray by imputing extortionate prices for a book he had published. The jury returned a verdict in favor of Mr. Murray and assessed the damages at $37,500. This incident brought up the whole subject of ‘letters to the editor’ and tended to emphasize the value
of this department as an index to current opinion. As The Spectator says: "Letters to the editor" should be the home, not of procured opinion, but of the facts (the nature of public opinion itself being a fact) which the editor has to face. He may try to direct facts, to secure that they shall or shall not occur again, but he must not suppress them or tamper with them as such. We believe this criticism from the readers to be an instrument for thrashing out problems and getting at the truth which is of first-rate value." We second the motion.

Trans-Mississippi Commercial Congress.

THAT was a curious blunder which the Mayor of San Francisco made in his speech of welcome when he spoke of San Francisco as "the westernmost city in the United States." The Congress before which he stood has been giving lessons in economic geography for 19 years, and one of the chief lessons has been to emphasize the importance of the westward movement of industrial development. As every up-to-date schoolboy, at least in Alaska, will tell you, San Francisco is situated east of the geographic centre of the United States, and if you sail from San Francisco to Unalaska or Nome, you will become impressed with the fact. This does not include the distant possessions of Hawaii, Guam, and the Philippine Islands, but only the continental portion of America and its peninsular projection into the Pacific Ocean. However, the Mayor made a speech that was scholarly; it was a credit to the wave of reform that placed him at the head of the municipal government of San Francisco. Assuredly his address, abounding in literary toches, in serious thought, in facts and figures, was a pleasant contrast to the drivel that emanated from the Governor of the State and the senior Senator. The sophomoric rubbish of the first and the puerile platitudes of the second were fitly representative of the sinister agency that placed these men in office. By no stretch of the imagination can such men be deemed proper spokesmen for the Commonwealth of California. Yet their participation in the opening of the Congress is not without encouragement, as indicating respect for a body of men engaged in the crystallization of public opinion. The Trans-Mississippi Commercial Congress is an extra-legislative parliament of the leaders in commerce and industry, assembling annually for the purpose of ascertaining the needs of the country west of the Mississippi river, and of formulating a demand for the fulfilment of such needs by legislation. The growth in importance of this Congress, of the Mining Congress, and of the Irrigation Congress, is proof direct of the unrepresentative character of the National and State legislatures; it is a recognition of the fact that the Forakers and the Baileys, the Platts and the Depews are sent by the big corporations to safeguard special privileges and selfish interests. Of course, all the gentlemen participating in these annual gatherings are not altruists, nor even undiluted patriots, but for the most part they are prompted by public spirit to give their time and energy to deliberations designed for the common good. For instance, we note with pleasure the participation in these proceedings of such men as Mr. Thomas F. Walsh, a man who by sheer luck and the generous laws of the United States was able to become possessed legally of a marvellously rich portion of the public domain in the form of a gold mine. What is more fitting than that a mine operator enriched by millions extracted by him with the permission of the State out of the mountains of Colorado, should now devote his leisure to public service. Whether he be rewarded by the Presidency of the Congress, or later by a Senatorship, is neither here nor there, save as it may place the seal of public approval upon his services to the community. With even greater pleasure we note the participation of Mr. Benjamin Ide Wheeler, the statesman who is president of the University of California, whose splendid speech was an oration in that it smote those chords of true feeling to which all men vibrate when at their best. Nor were we sorry to see Mr. J. C. Stubbs, the traffic manager of the Harriman railroads, endeavoring to beguile the thoughtless by a few soothing remarks. It was a sign of the times, as testifying to the desire to placent the wave of criticism that has threatened the big manipulators of railroads and railway shares. Another speaker, who spoke on an important topic, was Mr. John J. Barrett, to whom Nature allotted a voice of rare resonance not often used to such good purpose as when this week he made a vigorous plea for the stimulation of sea-going traffic between the port of San Francisco and the Latin-American republics to the southward. Truly the wretched steamship service between the cities on the Pacific Coast of North America and those of South America calls for condemnation. We are glad to note a recent improvement; for the Canadian Pacific Railway now runs comfortable steamers from Vancouver to the west coast of Mexico, and a French line makes calls between San Francisco and Valparaíso. The trade of South America is being diverted to England, Germany, and Japan, mainly because the American commercial agencies have neglected to take adequate interest in the maintenance of a seaboard traffic with the rich regions of our neighbor continent. We thank Mr. Barrett for raising his fine voice to such good purpose. The California Traffic Association passed a resolution strongly condemning the insufficient service afforded by the Pacific Mail Steamship Company between San Francisco and the Isthmus of Panama. Mining interests were to the fore when Mr. James L. Calhoun, secretary of the Mining Congress, made an argument for a Bureau of Mining in the National Government. This seems assured at the next session of Congress, and we hope it may prove a valuable aid to the regulation of an industry that has played a dominant part in the development of the United States. But the most striking feature of the Congress was the keen interest taken in the message from the President of the United States. It was announced that Mr. William R. Wheeler, Assistant Secretary of Commerce and Labor, would bring a special message from Mr. Roosevelt, and it was noteworthy that many men sat during the weak inanities of the addresses of welcome in patient expectation of hearing something worth while from the virile
reformer at Washington. Mr. Wheeler did not deliver his message with any special grace, but it proved deeply suggestive, for the President sent word that the Panama Canal would soon be completed, and steps would then be taken to divert the tide of European immigration from Atlantic seaports to those of the Pacific, thereby creating a new channel for the influx of population to California and her neighbor States. Information from other sources leads us to doubt whether the Panama Canal will be finished as soon as the President assumes, but we hope he is right and our informants wrong. In any event, there is food for thought in this idea of diverting immigration to the Pacific States. On the whole, we only regret that the Trans-Mississippi Congress was in session so short a time, and that so large a part of that brief period should have been wasted in addresses of welcome that were merely sound, signifying nothing.

Should Mining Engineers Advertise?

Our contemporary at London asks the foregoing question, and apparently deems it inexpedient to provide the answer. We appreciate that it is a difficult problem and it is best let alone unless tackled frankly, for in matters of this kind the only chance of arriving at a decision by means of discussion is to be outspoken. Mere coquetting with the subject ends only in a verbal flirtation. And it is worth while to reply to this question sincerely, for it is one of general interest to the profession, as affecting the unwritten code now in process of development. No discussion is profitable that starts without a definition of the terms employed. In our query the salient word is "advertise." What is the significance of this term? To 'advertise' is 'to make known by public notice, to publish abroad' certain facts concerning an article of commerce or a commercial undertaking. Advertisement ordinarily involves a publicity favorable to the making of money thereby. In England the idea still survives that anything savoring of the shop-keeper is necessarily vulgar, and the attainment of public notice by methods in any way resembling the placing of wares on a counter is held to be inherently reprehensible. Therefore a professional man will allow others to discover his merits, and prefers even to freeze in splendid isolation rather than invite the warm glare of publicity. For a kindred reason, geology in Britain seems the study of ore deposits, and it is deemed gentlemanly to investigate mulluses rather than ores, scenery rather than outcrops. This is part of a heritage of make-believe and the offspring of a mental snobbishness inseparable from a condition of society in which a foolish Duke is regarded with more respect than a wise carpenter. In America we see things otherwise, not that our people are superior in their intelligence but simply more free to think for themselves. Occasionally the result is chaos, but occasionally also the result makes for light. In the spacious environment of a new country, amid the fresh air of mountain and prairie, some of the sophisms of the old world look like mildewed spider's webs, only seen to be brushed aside. To us commerce is no less noble than idleness, wealth won by industry no less honorable than that which is inherited, and a professional man no better than a workman, except in so far as he can prove himself a better citizen. To the American there is no taint in commerce, and as science becomes applied to industry so also business methods are brought more generally to the aid of professional practice. One of these is advertising. In a community that accepts competition as a stimulant to efficiency the idea of excelling carries with it the notion of excellent. The young engineer hopes to get out from among the indistinguishable herd, from among the "others" and the "also ran" of life. The older men with an established position recognize that it is expected of them to show their mettle when challenged, to be ready to step to the front, to maintain the healthy pace of an invigorating rivalry. To blow a horn or to hire the town-crier is to provoke derision, for a sense of humor obtains; to advertise individual ability after the manner of a soap manufacturer is undignified and therefore ineffective; to provoke constant notice is tiresome. Other ways are available, among these the publicity obtainable from a venal and sensational daily press is the most obvious, but it fails because the medium is not persuasive. Moreover, even commerce does not kill tact, even money will not exterminate taste. The American mining engineer knows usually what is befitting a professional man, for such knowledge is innate among men of sensibility on both sides of the Atlantic. So there remains the publicity of success, the scholarly distinetion of the pen, and the plain advertisement of a directory. Owing to the facility of modern methods of communication, whether by post or telegraph, by telephone or aerogram, the names of those who win notable success as technical advisors or as managers of important mining enterprises are speedily whispered, if not shouted, along the copper wires, and instant celebrity is the reward of the man who proves extraordinary merit. To those at whose doors opportunity does not knock as loudly or on whom fortune does not smile as blandly, it remains to assert their preparedness for special work by contributing to the mass of written information upon which progress is largely based. Some there be who have the time both to do things and to write about them, to ruminate and to crystallize, to help themselves and to help their brothers at the same time. Finally, while it is not good form to shout from the house tops, to subsidize the daily press, to claim inspiration denied to others, or to offer services after the fashion of a corybantic vendor in the street, yet we think it desirable for an engineer to place his name and address in a list containing the active members of his profession, to the end that his friends may know where he is, and what he is doing. Such advertising involves no claim to pre-eminence, necessitates no bombard, and violates no notions of decorum. We are not aware that the mining profession in America lacks any of the dignity of the same profession in Britain, nor can we see how the commercial idea has contaminated the fountains of scientific investigation. Our answer to the query is: Yes.
Personal.

H. F. Collins is in Cordova. Arthur Lakes is at San Diego. Charles S. Henshaw is in Nicaragua. Francis Drake is here from London. E. O. Dau is at Guanajuato, Mexico. Charles Butters is at Copala, Mexico. J. Power Hutchins is at Pierce, Idaho. S. H. Loram is stationed at Valparaiso, Chile. G. S. Tyler, of Gaston, Cal., is in San Francisco. A. G. Kirby, of Goldfield, Nevada, is at New York. S. F. Emmens is on his way from Paris to Washington. W. F. Ferris was in San Francisco, on his way to New York.

A. L. Clark has returned to San Raphael from Reno, Nevada.

Algeron Del Mar is examining mines at Rawhide, Nevada.

M. H. Kuryla is with the Esperanza Mining Co., at El Oro, Mexico. Robert Linton, of New York, was here, on his way to Los Angeles. Charles Hole is manager of the Esperanza mine, at El Oro, Mexico.

George A. Denny is examining the Los Anoes mine, at Sultepec, Mexico.

K. Y. Sheid is assayer for the Nome Bank & Trust Co., at Nome, Alaska.

S. E. Brehm has moved his office to 422 Montgomery St., San Francisco.

Edward L. Spencer has left Grass Valley, California, and is now at Berkeley.

C. M. Yezmans, formerly at El Oro, Mexico, has been surveying a railroad in Java.

Harry D. Griffiths is general manager of the Tonooh mines, in the Malay Peninsula.

Arthur Feust is superintendent of the Standard Consolidated Mines, at Bodie, California.

L. S. Austin has returned to Houghton, from an extended journey in the iron mining region.

Robert M. Raymond is spending a few days at El Tovar, on the edge of the Grand Canyon, Arizona.

Hugh R. Van Waakkes is at Valdez, Alaska, on his return from the copper mines on Chitina river.

Costandy E. Palmer is now consulting engineer, instead of general manager, to the Guanajuato Development Company.

Thomas F. Walsh, of Denver and Washington, has been elected president of the Trans-Mississippi Commercial Congress.

Wm. L. Chapman, superintendent for the Golden Jubilee Mining & Milling Co., at Coffee, Trinity county, is at the St. Francis.

Sumner E. Brown has gone to Alunite, Nevada, to serve as assayer for the company organized by Robert T. Hill, of New York.

Willard S. Morse will leave Salt Lake City and return to New York, in the service of the American Smelting & Refining Company.

S. J. Truscott has resigned as manager of the Redjang Lebong mines, in Sumatra, and has opened an office at 43 Threadneedle St., London.

Dividends.

On October 3 the Bunker Hill & Sullivan Mining & Concentrating Co. paid dividend No. 122, of $75,000. This makes the amount of dividends paid since January 1, 1895, $10,521,000.

**General Mining News.**

**ALASKA.**

The London firm of Leopold Hirsch & Co. has taken over the interests in Alaska of the Valdez-Yukon Railway Co. and the Hinshard Elliott Mining Co. The contract given the London capitalists three years in which to complete the railroad to the interior copper districts. In addition to the main line to the copper mines, a branch is projected to run from the Copper river across the Tanina divide 60 miles to the Matanuska coalfields, where the Company also owns property. As soon as the coal mines are reached smelters will be constructed at some point on Valdez bay. If climatic conditions are right, preliminary railroad work will be done this fall, otherwise nothing will be done until the spring. The Valdez railroad will compete with the Morgan-Guggenhein road now building from the largest claims in the Nome district. Robberies of this character have of late become more and more frequent. The four big claims that have just been robbed are the Besse, Lakeview, No. 13 Dry Creek, and No. 13 Osborne Creek. Just how much gold has been stolen is not known, but it is believed that the robbers made way with thousands of dollars worth of dust. —It is reported that Ivan Brostrom has found a quartz vein 20 miles up the coast from Nome which is 300 ft. wide, giving assays all the way from $5 to $16. Two men are at work sinking a shaft.

F. Darlington was in Nome recently investigating the prospects for a plant on Chicago creek to furnish electric power to the Candle, Inuachuk, Good Hope, and Kougakon mining districts. The plan is to use the Chicago Creek coal and generate electricity at a high pressure for transmission to the various properties, constructing machinery required. —The Nome D. & M. Co. has decided to start a gasoline drill at work on its property in the Tishon River country. The holdings consist of a large tract of dredging ground.

**ARIZONA.**

**COCHISE COUNTY.**

The San Simon Copper Co. is about to start assessment work on its group of 49 claims near Paradise. Marshall Estes will have charge of the work and employ five men. —The contract for the annual labor on the Rabbit group of claims, near Dunn Springs, has been let to W. H. Smith. —The Uncle Sam shaft of the Copper Queen has been equipped with cages instead of the buckets that were in use since the beginning of work at that shaft.

**GILA COUNTY.**

At the Superior & Boston property a good start has been made to sink the new working shaft for the Great Eastern mine. The location of the shaft is on the Copper Money claim of the Collins & Doyle group, which has been acquired by the Superior & Boston Co., and is distant from the present Great Eastern shaft over 1000 ft. in a northerly direction. —It is probable that the Arizona Commercial Copper Co. will build a smelter on its Pontiac claim, 300 or 900 ft. northeast of the Eureka shaft. It is expected that the contracts for structural steel and machinery for the plant will be placed within the next few weeks, and the smelter should be completed late in the spring of 1909.

The capacity of the plant is to be 300 tons, but will be arranged with the expectation of its enlargement when greater capacity is needed. By the time the smelter is ready to go into commission the Eureka shaft will have been sunk several hundred feet and levels at 625 and 750 ft. well advanced. Development at the east end of the Black Hawk, below the 500-ft. level, will also be in progress, and there is little doubt that the ore supply will be ample. —The Globe Consolidated has started shipments from its Gem mine to the Old Dominion smelter. The vein recently found on the 12th level has widened from three to seven feet, and the latest assays show 6 % % copper.

**Pinal County.**

(Special Correspondence.) —The Vekol mine, which in the past was second only to the famous old Silver King mine in the production of silver, has resumed work under new ownership and management. The mine is situated in the Vekol range, 35 miles south of Casa Grande. The ore lies in irregular chambers in a hard carbonate of lime, which has the appearance of having been crushed to nut size and then re-cemented by calcareous solution. Talc seams run from one ore chamber to another, and were formerly an unfailing guide in tracing orebodies. The property is now owned and controlled by the Vekol Mining Co., which was organized a year ago by E. S. Garnett, of Cordova. —Reports from Fairbanks indicate a continued drought and consequent inability of the miners to make clean-ups. Every one is hoping for rain before the close of the season. —If the gold he washed the last thing this season, it will likely be too late for shipment to the outside by steamer, in which event large shipments may be made over the winter route. Sometimes gold is sent out of the country in winter so as to get it invested and begin to get interest on it rather than let it lie idle for six months. —The Yukon Gold Co. is arranging to group virtually all its properties on Bonanza, Eldorado, Hiniker, the Klondike, and their tributaries in one group for representation. They are to be made appurtenant jointly to the pipe line, the dredges, the conveyors, and other such works as the Company maintains. The properties have been maintained by these workings in the past, but in several groupings. The claims on Hiniker alone owned by the Company aggregate 223. This will be the largest grouping of claims ever made in the Territory by one concern. —Reports from Last Chance indicate a successful season, plenty of water, and many operators. On Last Chance are plants operated by Dolan, Collins, Yonkins, Day, and Wilson & Townsend. Dolan has a plant on Treasure, and Dolan & Collins on Faulkner. —Slick-box robberies have been made within two weeks on four of the
Alhambra, and William Fortsch, of Casa Grande. This company took over the six mines belonging to the old Vekel group and 46 other claims. Active work was begun last March under the management of Mr. Fortsch with a good force of men, since which time work has been pushed with marked success. A double-compartiment shaft is now down 350 ft., where a large supply of water was struck simultaneously with reaching a promising orebody. Stabilized at the 120 and 350 ft. levels and drifts are being driven both north and south. Within two or three weeks the shipping of the high-grade ore to El Paso will commence, and if returns are satisfactory two carloads per week will be the regular shipment. The mill, which has a capacity of 40 tons per day, will be put into commission in a week or two. H. R. Neufitt, of Denver, is now at the mine and will sample the dumps, containing over 350,000 tons of ore, which, from experiments already made, will yield over $1,50 per ton net. Mr. Neufitt will also determine the value of thousands of tons of low-grade ore which has been stored away in the cross-cuts and stopes of the old workings. The ore blocked out in these workings embraces more than six miles of underground work, from which it is claimed $7,000,000 in silver and lead ores have been extracted.

Phoenix. October 2.

YUMA COUNTY.

The Castle Dome mine and the first north extension of the Flora Temple have recently been transferred to James M. Barney, a descendant of Col. James M. Barney, who with others located the Castle Dome in 1871. The new owner has interested several citizens of Phoenix in the property and it is hoped work will again be started. In the first year of its existence the Castle Dome produced 500 tons of ore averaging 6% lead and 50 oz. silver, and up to 1881 it had produced over $2,000,000.

CALIFORNIA.

NEVADA COUNTY.

(Special Correspondence.)—Owing to the lack of sufficient water in the Uruguay, the several mines are suspended operations, the Empire has hung up 20 stamps and has reduced the working force one-third. At the North Star, the Pennsylvania, and one or two others work is carried on steadily by the extensive use of steam. The shaft at the Hill mine has been watered, a 12-hp. gasoline hoist installed, and sinking and driving are about to commence. The shaft at the Morydena is down 73 ft. and the north adit from this point has cut a four-foot vein of good ore. An adit will be driven from the west side of the hill to connect with the shaft, 500 ft. distant. A group of English capitalists are interested.—W. L. Hemmington and J. L. Green have taken a long-term bond on the Rose Hill mine at Nevada City and will proceed with active developments. Three shifts of men will be employed. The Rose Hill has paid idle for eight years, although considered a meritorious property. C. D. Tregonning is superintendent.—The Wahptiti M. Co. has been incorporated at Nevada City to work the Black Bear mine near Rough and Ready. The capitalization is for $250,000, par value of stock $1.

Grass Valley, October 4.

SACRAMENTO COUNTY.

Eleven men are under arrest in Sacramento suspected of having had a part in the recent theft of amalgam from the Hafroid-Gerber ditches near Folsom, four of whom have already pleaded guilty. It is estimated that between $15,000 and $25,000 has been stolen, and only $500 has been recovered. The owners of the dredge will institute a civil action to secure possession of the plunder.

SHASTA COUNTY.

The Black Tom Mining Co. is sinking a shaft on the Scorpion mine, at French gulch, and is now cross-cutting and driving on the 100-ft. level. There is one vein four feet wide that averages $25 per ton milling ore. There are two other veins opened up on the adit level which average from $7 to $10 per ton. The Company will continue sinking the Scorpion shaft to the 599-ft. level, when it will open up and develop the orebodies on each level. Men have started to re-timber the O’Neil adit at the Niagara mine and also re-timber the St. Aubrun wine, opening up and developing the orebodies which have been worked out above. The Company has started to erect a new 14-stamp mill and expects to have the stampes dropping on ore within sixty days. The force consists of thirty-five men.

The Delta Coffin is again taking up the subject of construction of narrow-gauge tram or railroad from Delta on the Southern Pacific railroad to a point six or seven miles up Dog creek, where the mines are situated. M. E. Dittmar and S. T. White, of Redding, are interested.

SIERRA COUNTY.

The Morse Bros. are doing the assessment work on the Brown Bear claim on the upper end of the St. Charles Hill ridge, between Snow and Fiddle creeks. It is the intention of the owners to drive an adit to strike the channel.

The mill at the Gray Eagle ran for only a few days last week because of a shortage of teams to haul ore. More have been obtained now and the work is to be continued without interruption. Two new shoots have recently been opened up in the adit, and one shows considerable free gold.—Six men are building the dam at the power-site of the Mexican mine, a mile from Downieville on the South Fork. The dam will be 18 ft. high, giving a fall of 30 ft., which should develop about 300 hp.

The shaft on the Rock creek, being sunk by Mott & Morrison, has reached bedrock and work has been suspended until next spring.

SISKIYOU COUNTY.

A company of New York capitalists have secured the Granite mine, on Humbug creek, and are preparing to push the work of development on a scale well justified by the showing. This property has been a producer for over 20 years, but has never been worked properly. Charles A. Mitchell has charge of the new work, and will immediately start to sink a shaft to a depth of 500 ft. on the vein.

The big ditch of the Klondyke Mining Co. which is to take water from the Klamath river and generate electric power to operate the new Huntington mill is nearing completion. There is sufficient water to develop 500 hp., but only 150 will be used at the present time, the remainder being sold to neighboring properties.—Shore & Howson have taken a contract for a 130-ft. adit on the 220-ft. level of the Highland mine. The Highland is one of the mines which has furnished so much specimen ore that has been used in mining exhibits all over the coast.—Gardner & Weed have a force of men repairing flumes and clearing ditches along the Kidder creek and Shackleford ditches, the former for 500 ft. at the latter, and cutting ditches to the new ground they are preparing to pipe as soon as water starts. They also have a force of men sinking upon a 50-acre tract newly purchased, in order to test more thoroughly the value of the auriferous gravel. The Company is preparing for one of the biggest runs ever made in this county, and as they have four ditches they are able to do double the work of any company that has hitherto worked the deposits along the Quartz Valley mountains.

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence.)—A rich strike has been made on the Brighton property at the French gulch, consisting of $40 silver, lead, copper, and gold ore having been uncovered that is from 15 to 24 in. wide. The west drift has been run 75 ft. from the 900-ft. station of the shaft, while the east drift has been extended for 55 ft. The ore-shoot is showing for the entire distance. This property has levels every 100 ft. to the 500-ft. station, from which point sinking was continued until the bottom measured 920 ft. from surface. In the near future levels will be started at the 600, 700, and 800 ft. stations. During the last year regular shipments have been made, and effort is now to be made
to send out an increased tonnage. The property is equipped with a complete plant of machinery, as well as a 70-ton concentrating plant. J. C. Sturdevant, of the company, is manager. W. J. Guard, of Silver Plume, has taken a three-year bond and lease on the Martelon and the Mitchell lode mining claims, situated on Sherman Mtn., the bond being for $5000. A company is now in process of organization and work will be put under way at an early date. From the surface workings ore has been mined of a high grade, but it has been decided to take a cut to intersect the vein at greater depth. —The Wallace Con. M. Co, has leased to Chester A. Finch the Wallace group of ten lode claims, in the Cascade district. The consideration is given at $5000 cash. Mr. Finch will organize a company and start operations at once. —Kavanagh & Co., leasing on the Wisconsin, are sending out regular shipments of 350-oz. silver ore. Since the adit intersected the vein above the old stopes in the upper workings the drift has been run for 75 ft., with a streak of ore that is from 10 to 15 in. wide showing all the way. Stopping has been started and in the future the output will be increased. Directly below these workings a production of $400,000 was made a few years ago from a block of ground 400 ft. long and 300 ft. deep. —The stake of ore in the Sporting Times, Alpine Mtn., has widened from 6 to 10 in. during the past few weeks. It is of much more serious and long-est assured than any other in the district and assays show 3 oz. gold, 40 oz. silver, and 61% lead. It is the purpose of A. H. Colburn, the owner, to continue the drift for 50 ft., at which time stopping will be started. The showing in this property is such that a number of owners of mines have signified their intention of starting work at an early date. —The showing at the Bellevue-Hudson is better than the best during the last six months. M. Mouatt, who is operating a block of ground on the Anamosa vein, is running a drift to the east and is following a streak of ore that is from 14 to 16 in. wide, which assays from 150 to 175 oz. silver. A winze is being put down from the sixth level, in the bottom of which a 16-in. streak of ore is showing. Driving will be started as soon as a depth of 75 ft. has been attained. The Holmberg M. & M. Co., owning the property, has just installed a washer near the portal of the sixth level and now a large amount of dump matter is being treated. This stuff was thrown away during the early history of operations, when no ore was marketed that was worth less than $100 per ton. J. A. Holmberg, of Denver, is manager. —J. G. Roberts, of Idaho Springs, has installed a number of rough jigs at the dumps of the Lamarr mine and is handling a heavy tonnage of dump matter. After crushing, the product is sent to the Jackson mill, where it is concentrated, and fair returns are being realized from the process. —The Colorado Central is sending out more ore today than at any time during the past year. On the Ocean Wave level, F. A. Maxwell, the lessee, is running a drift on an ore vein that is fully 18 in. wide, and from recent shipments returns varying from 500 to 700 oz. silver per ton have been realized. Stopping is also in progress to the east of the Ashcroft stope and a good tonnage of ore is being mined. —Shipments will be started shortly from the Mountain Quall mine, up the gulch between Griffith and Alpine Mtn. In the breast of the adit there is showing a streak of $30 silver-lead ore that is much desired by the Denver smelters. M. L. Avery, of Georgetown, is owner. Georgetown, October 3.

GILPIN COUNTY.

A good strike is reported from the 150-ft. level of the Champion property in the Phoenix district, where an 8-in. streak of smelting ore is reported to carry 2.60 oz. gold, 1.6 oz. silver, and 15% copper. Ore is being hauled to the Champion mill which is reported to be giving average returns. —Arrangements are being made for the installation of another 69-hp, boiler at the Evergreen property in the Pine Creek district and some alterations and improvements are to be made in the new concentrating mill, which it is believed will effect a higher extraction. W. H. Grayson is manager. —Weiskotten & Ward, who are interested in the Victor property on Mineral hill in the Phoenix district north of Empire, have organized a company of Eastern people and are making arrangements for the active development of the property. Mr. Weiskotten will go East in a few days in the interests of the company. —Miller, Mellow & Co., operating the East Leavenworth mine in the Russell district, have made a big strike in the shaft at a depth of 220 ft. They commenced sinking during the early part of the month on a crevice which has since widened out to the entire width of the shaft and there is a smuggling streak about 20 in. wide which shows yellow copper and is better than the average grade.

HINDELA COUNTY.

F. C. Goudy and George M. Duke have purchased the Newport property, near Lake City and in the vicinity of Burrows Park. They have a force of men on development work and expect to continue work until the snow flies. They have a 7-ft. vein of fine mineral, much of it being shipping ore and the rest a good quality of milling ore. The test runs that have been made at the Durango smelter have turned out remarkably well and are most encouraging for the owners of the property. Next summer, if conditions justify, a reduction plant will be erected and the Newport will become a heavy producer and shipper.

LAKE COUNTY.

The Wire Patch mill, which was partially destroyed by fire a few weeks ago, has been practically re-built, and connections have been completed with the lines of the Central Colorado Power Co. The mill was put in operation, treating the ore from the Wire Patch adit as well as that from other mines in Summit county. — Favorable work is being done on the Black Prince property on Breece hill, which is being operated by Vernier & Shipley in connection with the Highland Chief mine. Both are producing good iron ore, and shipments to the Leadville smelter have been regular.

SAN JUAN COUNTY.

A new cross-cut 80 ft. long has been driven on the Golden Fleece and Scotia properties, which gives a depth of from 40 to 100 ft. below all the old workings. This new work has cut a vein of shipping ore which gives returns of 1½ oz. gold and 207 oz. silver per ton. The company is driving both ways on ore in this new vein, and will also sink a winze. —The mill on the Gold King was started recently for the first time since the fire on June 6. Three hundred men will soon be employed in the mine and mill. The mine was found to be in good condition.

SUMMIT COUNTY.

The Little Salle Barber property, on Baldy Mtn., near Breckenridge, is putting in a new steam hoist. The shaft is 170 ft. deep and the infow of water is so large that a pumping plant may be necessary. —The King Solomon adit, at Prisco, is now in 2045 ft. and work is progressing with 25 men employed. A drift in vein No. 2 has opened up an orebody assaying about $200 per ton. —The management of the Penn Ore Co. has put two shifts at work in the new Helen adit, and is expecting to strike some payable orebodies before long. —Operations will soon be resumed on the new Country Boy adit, the breast of which is now 1100 ft. from the portal. One of the richest streaks of zinc known in the camp was struck in this bore. —The hull of the Reiling dredge was successfully launched in the Moleska pit last week, and the work of installing necessary machinery on the boat is now going forward rapidly, with as many men employed as it is possible to handle. —H. B. Barnes has contracted to install an air-compressor and Leyner drills at the Foremost mine, near Prisco. A. L. Moon is manager of the Foremost. At the June mine Mr. Barnes recently completed the installation of Temple-Ingersoll air-drills. Both properties take power from the Central Colorado Power Company.

TELLER COUNTY.

The main working shaft of the Index M. & M. Co., together with the surrounding territory owned by that corporation, has been secured under a two years' lease by Crip-
ple Creek and Eastern parties and operations have already commenced. A leasing company is in the course of formation and will shortly be incorporated when the identity of the leasing company's officials will be made public. The shaft on this Gold Hill mine has already sunk to the 900-ft. level and extensive development work on a systematic plan has been determined on. Two promising veins, the northern extensions of Pointer and Keystone leads, are being explored in the two deep levels at the 900 and 700-ft. points. Connections between these two levels is to be made with all possible speed by raise and winze, so as to insure the thorough ventilation of these deep workings and the veins mentioned are to be exploited by driving to the limits of the estate.—Lambert & Boden, lessees upon the surface workings of the Dearborn claim on Globe hill have opened up a new surface deposit and are working on it in a general fashion at the rate of $15 per ton. This ore is highly oxidized and can be milled at a minimum expense. In the early days of the camp teams and scrapers were used for the mining of similar ore and should the deposit prove to extend over a large enough area, the same method may be adopted by the present lessees.—The Union Leasing Co., operating on the Deadwood mine on Bull hill, has opened up a promising ore body at the 450-ft. level and is practically driving machine drills from a four-foot vein, carrying from $19 to $28 per ton. The total tonnage shipped from the Cripple Creek district during the month of September amounted to 67,313 tons with a bullion value of $1,966,080. These results are remarkable for the fact that, while the tonnage shows a decrease of 1,575 tons over the month of August, the bullion value shows an increase of $65,316.

IDAHO.
SHOSHONE COUNTY.
(Special Correspondence).—The suit of the Stanley Consolidated Mining Co. against the B. H. & H. Co., by which the former sought to close down the Hercules mill and recover $25,000 damages for tainting alleged to have been dumped on the Stanley ground, has been withdrawn in Spokane. It is understood that amicable arrangement has been made out of court.—The Hecla mine and mill at Burke closed for the afternoon of October 1 in honor of the funeral of J. R. Smith, president of the Hecla company, who died in Chicago last week.—The men at the Copper King property, in the Mullan district, are at present engaged in the installation of the new compressor to be used in the driving of the adit for which three assessments of one cent each were recently levied by the Company.—Work has practically been suspended on the Bear top mine, at Murray, and it is not expected that there will be any resumption until the construction of the Idaho Northern railroad has been completed. This is regarded as the next mine in the Coeur d'Alene to join the dividend list. It is estimated that there is already more than $500,000 worth of shipping ore alone between the two levels, in addition to thousands of tons of concentrating ore. As far as can be learned it is the intention of the Company to ship about 15 cars per month as soon as the railroad is completed.—The directors of the Helena-Prisco No. 1 Co. have declared a dividend of 10 cents per share, which is paid from the revenue of the mine at Latulippe and will now develop the entire group. It is the intention of the Company to run a 600-ft. adit to give a depth of between 700 and 500 ft. Work has already been started.—The grading for the 1600-ft. flume at the Coeur d'Alene Vulcan property has been completed and work on the installation of the flume itself will commence at the illustrate of next month. The work on the dam at the property is almost complete and as soon as the flume has been done the men will start on the installation of the big new compressor.—The Charles Dickens mine, at Wardner, has been suddenly plunged into financial difficulties to the surprise of many stockholders in this part of the country, who had been in hopes that the better condition of the metal market would allow this Company to join the dividend list. The first suit against the Company of any size was filed by A. D. Gritman, manager of the property, and is for the recovery of about $54,000 on promissory notes secured by a mortgage on its property and mill. This suit has been followed by a large number of smaller suits, one of which contains assigned claims to the extent of almost $30,000. Just what action will be taken remains to be seen. So far the Company has been unusually unfortunate, having had its mill destroyed by fire last year almost as soon as it had been completed, while its successor had a narrow escape from the same fate during a forest fire this summer. The new skill has been opened up in the property of the Champion Copper Co., in the Stevens Peak district. The ore has an average value of about 16% copper, and was found in a drift about 700 ft. long, at a depth of 600 ft., but so far the strike has not been exploited to any extent.—Development on the Paragon and the Chicago-London, two of the most promising mines in the whole of the North Side district, is about to proceed. Some time ago work was stopped on account of the lack of power to run the 15-drill compressor with which both properties have been developed. For the present work will be continued by hand until the power supply is regained.—John E. Steen, president of the Granite & Allie Co., on which a suspensory order of ore was recently made, has been announced that the shaft at the property is to be sunk another 100 ft. into the oroboy. After cross-cutting the vein at a depth of 100 ft. a drift was run 25 ft. along the granite foot-wall through a solid body of ore. The adit was run through 24 ft. of ore, five feet of which is good shipping quality and the rest good concentrating ore. Mr. Steen is of the opinion that the oroby is 900 ft. long, as the vein has been opened for that distance by means of cuts and shafts. This property was at first supposed to be a gold proposition, and a stamp-mill was erected which is now to be converted into a concentrator and shipments are to commence as soon as the Idaho Northern railroad is completed.

Wallace, October 3.

MISSOURI.
JASPER COUNTY.
(Special Correspondence).—The past fortnight in this district has been characterized by a number of important developments. Perhaps the most notable was the oroby discovered at the Midnight mine, in the Belleville camp, near Joplin. A large underground cave was broken into which is filled with large houlders of pure zinc-blende and galena. The cave is approximately 100 ft. square and one side is richly lined with ore, while the other three sides show a small quantity. The floor is gilded with debris, among which is a large amount of turf. The drift is at an elevation of 140 ft. and ore has been enclosed to a point 20 ft. lower. The mill is running steadily turning out from six to ten tons of zinc-blende and two to three tons of galena per shift. Another rich strike has been made in the Leadville Hollow camp by the B. H. & H. Co. on the Granby M. & S. Co.'s land. The ore was found at a depth of 24 ft., and during the first week the Company took out 63,000 lb. of cleaned ore. The second shaft is a continuation of the same deposit found in the adjoining Try More and Leonard leases. The first shaft sunk on the Granby land to catch this run of ore entered a limestone bar and was abandoned.—A rich deposit has been opened in south Joplin by I. M. Gardner & Son on the Roaring Springs land. The orebody was found at 85 ft. and a face of ore 9 ft. high by 14 ft. wide is being worked. The ore is in soft ground which has been washed for some weeks, the ore being treated on board jugs. A large crush-pile has accumulated which will run about 15 to 20% zinc-blende with some galena. Two shafts are in ore, though only one is used for hoisting; the other is used for pumping.—A body of free zinc ore has been opened on the Turkey Creek by Snyder & Watkins. A shaft was sunk some years ago, but because of excessive water it was abandoned without reaching the orebody. The present company has re-opened the old shaft and started driving.
ground was drained with little difficulty. A permanent derrick has been built and hand jigs are being installed. A portion of the ore occurs in large nuggets, while the larger part is very fine, and when panned out runs high in good-grade ore. A drill hole east of the shaft is in ore at the same level. A rich deposit of galena and zinc-blende was found in an old shaft abandoned as worthless at Prosperity. The Lewis Mining Co. opened up the shaft, and after sinking two feet deeper penetrated the orebody. The material is very free and runs as high as 15% concentrate.

The Oronogo Circle No. 5 is building an 80-ft. extension to the mill, to be used in treating sludge. The plant has not been doing this work adequately, and the new portion will be given entirely to saving the fine which has been a problem in the past. Eleven new tables will be installed to treat the fine. The same company will build a sludge-mill to handle the fine from plants No. 1, 2, 3, and 7, but this will not be done until later. When the improvements are installed the Oronogo Circle No. 5 will have the most complete device in the district for the treatment of sludge. The plant is the largest single producer in Oronogo.

Joplin, October 3.

(Continued from Correspondence.)—An important transaction was made in the Aurora camp when the United Zinc Co. leased all its holdings to the Magnolia L. & Z. Co. for a royalty of 10% on two tracts and 20% on a third. The higher royalty was required from the third lease because this tract is more thoroughly developed and the new company has the use of all machinery. Prospecting includes 150 drill-holes, some of which are 250 ft. deep. A large number of shallow diggings are on the land and the recent rich lead strikes were made there. The land is said to have produced over $700,000 worth of ore. The Sand Ridge mines in the northeastern part of Aurora are to be re-opened soon. An extensive system of pumps and flumes were installed last year. Some of the heaviest productions made in the Aurora camp have been made at the mines on this tract. The company has one of the deepest shafts in the entire district. The Triple B mine at Aurora is being re-opened by Landau & Stone. A shaft was sunk last year to 50 ft., where a 15-ft. face of ore was opened up. The heavy rains of the spring caused the ground to cave. A new shaft is being sunk and the work will be hastened until the ore deposit is reached again.

Aurora, October 3.

NEVADA.

It is reported that silver and nickel ore have both been found on the Red Top claim of the Goldfield Com. Mines Co.—The Penn Florence lease, which owns the old Wins- ton block on the Cornishman claim of the Goldfield Flor- ence, has been re-organized. The capitalization has been increased from 600,000 to 1,000,000 shares. The new officers are: Lewis H. Rogers, president; W. B. Winston, vice-president; Thomas F. Manning, secretary and treasurer. It is the intention to begin active development work at once.

R. L. Hubbard, representing a minority stockholder of the Mohawk Jumbo Leasing Co., filed suit this week in the Dis- trict Court against that corporation and the MacMillan-Hol- leran Co., demanding the restitution of $45,000 alleged to have been wrongfully paid to 500,000 shares in the Mohawk Red Top Lease Co., and for the appointment of a receiver for the Mohawk Jumbo Leasing Co. The complaint alleges mismanagement of the latter company's affairs by the Mac- Millan-Holleran Co., and declares that the purchase of the stock of the Mohawk Red Top Lease Co., which is also controlled by the MacMillan-Holleran Co., was illegal. The Jumbo Consolidated will resume work at once on its Gopher claim, and sink the shaft and extend it to a depth of 250 ft. An electric hoist will be put in at the North Star shaft and cross-cutting will not be started until the 250-ft. level is reached.

Work has been started on the group of claims belonging to the Indianapolis Goldfield M. & D. Co. at the north end of the Montezuma range, two and one-half miles west of Indian Springs. The office of the company is at Frank- fort, Indiana.—The 200-ft. shaft on the Economist claim of the Old Kalstueck Goldfield Mining Co. is being re-embayed preparatory to sinking to the 400-ft. level. Diamondfield Jack Davis has begun work on block four of Com- bination No. 2, which he has under lease for 18 months. Goldfield and Los Angeles capitalists are interested with him in the property.—The National Ore Purchasing & Reduction Co. has been incorporated under the laws of Ariz- ona to erect and operate mills and carry on an ore-pur- chasing business. The first point of operation will be Raw- hide, where the company plans to erect a 50-ton cyanide mill, including a sampling plant. Options on ore contracts have been secured from the principal leases in the camp, arrangements have been made with the water company, and it is hoped construction will start at once. The proposed scale of treatment-charges ranges from $7.50 per ton on $15 ore to $25 on ore valued at $100 or over. Lochiel M. King and J. W. Heisner, of San Francisco, are interested.—The mines of Goldfield produced during the week ending October 3 a total of 2236 tons, of an estimated value of $282,675. During the same period the Tonopah mines produced 5741 tons, estimated to be worth $146,675.

LINCOLN COUNTY.

At Pioche the Golden Prince Mining Co. has found ore assaying 65% on, silver and 40% lead. This ore was found while stripping the vein in a westerly direction on the Black Hawk No. 2 claim, and is a surface showing. The shaft which the Alumite Mining Co. is sinking on its property, in the new camp of Alumite, in Railroad pass, has reached a depth of 51 ft., although the hoist is not yet in commission. The company is putting up substantial wooden buildings and evidently preparing for a permanent camp. The Searchlight M. & M. Co. is planning to begin operation with a full force in the near future. H. E. Car- ter, who is general manager, has recently returned from New York, where he was successful in selling the bond issue of the company. A 10-stamp mill, 100-ton cyanide plant, and a steam hoist have recently been put in at the mine.

The regular quarterly dividend of 25¢ per share of the Tonopah Mining Co. was declared last week, payable Octo- ber 21.—The little two-stamp mill at Manhattan, known as the Veith-Plamenes, which has been running constantly day and night on ore from that camp, will be closed down temporarily, pending the installation of five additional stamps, the machinery for which is now on the ground. A little later a cyanide plant will be added. The T. & T. Mining Co. has appointed M. A. McKnight, W. C. Pollard, and Wm. Roddick, of Rhyolite. The capitalization is 1,000,000 shares, par value $1. The claims of the Company are on the Tonopah & Tidewater railroad, about 100 miles south of Rhyolite, and have a good showing...
Special Correspondence.

LONDON.

I have often referred lately to the difficulties nowadays encountered by mining people on the lookout for the money necessary to acquire and open up properties. An unfortunate instance of this kind is to be found in the case of the New Great Wheal Fortune Syndicate, which I recorded a few months ago. It was formed for the purpose of acquiring tin mine and a china clay deposit in the Breage district, about half way between Falmouth and Penzance. The mixing up of tin and china clay in one formation is of doubtful advantage, and it appears to me that the working capital asked for, £12,590, is not nearly sufficient for one of the propositions alone. But no doubt at the time of flotation the directors expected there would be no difficulty in raising further funds if their preliminary operations gave encouraging results. As a result of the public flotation only £25,000 was obtained. The remainder of the issue had been underwritten, so the directors proceeded to allotment. This underwriting contract turned out to be purely speculative, such as is far too common in the City of London. Even men of sound standing are prepared to undertake the underwriting of new issues, knowing that the directors seldom dare enforce the contract if the issue is a failure. In this case the directors sued the underwriter for the amount due from him, and the suit was set down for hearing in the courts. Before the case came on, the underwriter owned up to the fact that he could not pay at once, but promised that if the directors would suspend litigation he would give six-month bills for the amount of his indebtedness, and forgo his underwriting commission. The directors accepted this proposition, and accordingly work was commenced at the tin mine last month. Under the circumstances it is not far to mention the name of the underwriter. The board of directors consists of Sydney Fawcett and two sound commercial men not connected with company-promotion or with other mining operations. Mr. Fawcett is the author of a book on tin deposits, and learned his tin mining at Mount Bischof, in Tasmania, in which mine his family hold large interests. He has relieved the underwriter of £1600 of his liability by taking up shares to this amount.

That doubt seem remarkable to many American readers that the number of persons employed in Great Britain and Ireland in mining and quarrying operations is over a million. During the year 1907 the total number so employed was 1,060,034, of whom 792,220 were engaged at mines and 87,514 at quarries. Of those employed at the mines, 776,456 worked underground. Of the 195,764 working above ground 58,04 were women and girls, most of whom were occupied in picking coal. The number of miners employed during 1907 was an increase of 49,053 underground and 10,551 above ground, as compared with the figures for 1906. The total employed at coal mines was 925,697, from which it is obvious that the coal mining industry is the backbone of British mining. There were 14,484 employees at the iron mines of Cumberland and Yorkshire, the former being hematite mines and the latter carbonate mines. Other mines employed 29,829 men, of whom 8500 were in Cornwall.

As regards the 87,514 people employed at quarries, 4233 were at the iron quarries in Lincolnshire, Leicestershire, and Northamptonshire, where ironstone is worked by open-cut. I believe that the number employed is greater than the above figure, for there are several workings that do not come under the legal definition of a quarry. According to the Act, a 'quarry' is an open working which is at least 20 ft. deep. Of the rest of those employed at the quarries, the numbers are divided quite equally between granite, limestone, sandstone, and clays.

During the last 50 years the precautions taken to ensure safety in coal mines have had a notable effect in minimizing accidents. In 1851 the death-rate among the underground workers was over 5 per 1000, whereas in 1907 the rate was rather less than 12 per 1000. The death-rate from explosions was 0.057 per 1000 during 1907. It is a rate which varies widely from one year to year, owing to the small number of explosions and their varying severity. The highest rate during the last ten years was 0.25, in 1905, when several accidents of unusual severity occurred. The accidents from falls of ground do not vary greatly, the rate being fairly steady at from 0.4 to 0.5 per thousand. The total number of fatal accidents during 1907 was 1283, involving the loss of 1398 lives. Of these, 1195, causing the death of 1279, happened at mining. The number of non-fatal accidents was 18, by which 14 men met their death. There were also 16 minor explosions in which nobody was killed. The total number of men injured, but not killed, in the 184 fatal and non-fatal explosions was 238. There were 567 fatal accidents due to falls of ground, involving 536 deaths, and 77 fatal accidents in shafts, causing 103 deaths. There were 239 accidents in transportation, killing 216 men. The causes, chiefly through negligence, were extraordinarily accidents accounted for 151 deaths. Above ground, 148 accidents involved the death of 149 men. Some indication of the systematic rules relating to safety in mines is given by the number of prosecutions of both masters and men for contravening the rules and regulations. During 1907 the masters' prosecutions amounted to 130, and the convictions to 57. There were 1064 prosecutions of the men, of which 1023 were successful. The greatest number of offenses were connected with riding on mine cars. There were 81 culpits found with pipes in their pockets, and 75 found sleeping while in charge of a safety lamp.

TORONTO, CANADA.

Miller's Revised Report on Cobalt Geology.—The Provincial Mine.—Activity in Cobalt Stocks.—Visitors to Camp.—Many Important Discoveries.—Explorations in Temagami Reserve.—Brazau River Coalfields.

The Ontario Bureau of Mines has just published a third edition of the report by Willet G. Miller, provincial geologist, on the 'Cobalt-Nickel Arsenides and Silver Deposits of Temiskaming,' originally issued in 1905, comprising much additional information, especially as regards the workings of Cobalt. The geologist discusses the mining areas where silver or cobalt occur. Mr. Miller in his preface states that it has not been necessary to make fundamental changes in the description of the geology of the ore deposits, his views as to the relationship of the rocks, the character and nature of the veins, and the economic problems of the camp remaining the same. Much work has been done in the interval, but no new type of orebody has been discovered, with the possible exception of the ore associated with the aplite of the Montreal River area. While both the silver-cobalt ores associated with the aplite of the Montreal River area, and those of the Cobalt area proper, are believed to have been derived from the diabase magma, the aplite ores appear to have come more directly from the magma, and can be classed as of aqueous-igneous origin, the Cobalt ores being of aqueous origin. The report on the Montreal River area by Cyril W. Knight notes the extensive area over which cobalt bloom in small quantities has been found in this region. Many of these small veins differ from the Cobalt type, being aplite dikes having the composition of a granite, but finer in grain, and containing few colored constituents, like mica or hornblende. These aplite dikes are supposed to have been formed by cracks appearing in the diabase as it cooled and contracted; they were subsequently filled with vein or dike material, which probably came from hot solutions given off by parts of the
still molten diabase. Small scales of native silver occur frequently in the apile. Some of the veins have the same general character as those at Cobalt, but sometimes they contain barite, which is not known there.

The report on the working mines contains a description of the Provincial mines, concerning which little information has been given. The shaft has been sunk 140 ft., with levels at 65 and 125 ft. On the first level, 450 ft. of driving has been done, and 70 ft. of cross-cutting, and a raise has been put through to the surface, 50 ft. east of the shaft, timber put in, and stopping begun for 90 ft. along the vein. Driving and cross-cutting has been done to the extent of 125 ft. on the lower level, and a raise to the first level has been begun. The plant comprises a 100-hp. return-feeding high-pressure boiler, a horizontal dust-collecting vessel, a Bandit air-compressor, compressing 500 cu. ft. of free air per minute, and a 7 by 10-in. Jencks hoist. Three air-drills are in operation, and 25 men are kept at work under the superintendent, S. Hunter. The noticeable feature of this report is what it omits. No information is given as to the value or prospects of the mine, the character of the veins, the amount of ore taken out or developed, or the results of the stopes made during the early part of the year. Such information has been repeatedly asked for, the public having a right to know the particulars regarding a government work. It is a question what private interests may be subserved by this secrecy.

In another respect the Provincial Government has been guilty of blundering or worse in relation to a matter connected with the mining interests. Frank Law, wild-cat promoter, after months of delay, was put on trial this week, charged with conspiracy to defraud in connection with the flotation of the Highland Mary Co. of Lander Lake. His counsel, G. T. Blackstock, theretofore moved his discharge on the ground that he had been called as witness in proceedings taken to secure the extradition of his partner, J. Rusby, to prevent a similar proceeding, the appeal of Judge Winchester referred the whole matter to the Provincial Attorney General, remarking that the case had been badly bungled by the Government officials. It now transpires that, although preliminary proceedings looking to the extradition of Russell, who was undoubtedly the leading spirit in the conspiracy, were taken in the winter, and the police after a long search succeeded in finding the fugitive at Detroit, Ohio, as soon as he was reported as in the Province, the Attorney General Foy, he peremptorily ordered the police to take no further action. The whole business has a singular aspect: but laxity of this kind has lately been characteristic of the administration of justice in this Province.

The interest in Cobalt continues unabated. Shipments are keeping up well, and important discoveries are of frequent occurrence. The present feature of the trade has been a large number of visitors. Last week a party of Montreal and Ottawa capitalists numbering about thirty, under the direction of Frank C. Armstrong and W. E. Hidden, of New York, inspected the leading mines, and this week 16 leading Detroit financiers and business men paid a visit to the camp as guests of E. N. Skinner, of New York. Shipments for the week ending September 26 amounted to 579 tons, from the following mines: Buffalo, 31; Cobalt Central, 55; Drummond, 30; La Rose, 75; McKinley-Darragh, 26; Nipissing, 115; O'Brien, 61; Right of Way, 20; Silver Queen, 124; Temiskaming, 30; and Temiskaming & Hudson Bay, 30. At the La Rose the force has been increased to 140 men, and the bluff at the north end of the property is being developed by adits. In adit No. 10 a vein was struck when in 92 ft., on which driving for 200 ft. has been done. The vein is 1 in. of ore assaying from 3000 to 4000 oz. silver per ton. A mine is being sunk on No. 3 vein on the adit level 50 ft. to the west of the shaft, and large nuggets of native silver have been taken out. Operations were recently started on the University, one of the properties embraced in the La Rose merger, resulting in a rich find in the No. 3 shaft at 23 ft., where two stringers were found with an average width of 2 in. of ore yielding over 4000 oz. silver per ton. At the Chambers-Feirland surface-prospecting last week disclosed three new veins. The Kerr Lake Mining Co.'s annual report gives the output for the year at 1,472,712 oz. silver, valued at $74,235.20, coming from the two or three levels in producing the ore, exclusive of the cost of the surface-plant, shows a total of $139,530, giving a gross profit of $64,023. Estimating the cost on the basis of an ounce of silver, the metal has been produced for 9½c. per oz. The Nipissing has employed a force of about 100 men during the summer in trenching, with a view to the discovery of new veins, which as found are marked on the map. The company has, in all, over 1000 men known to exist, but not half of them are being worked, the others being kept in reserve until underground development is further extended, when they will be tapped and operated. The Silver Queen, which headed the list of shippers last week, is having the ore on its dump treated at the Muggleby concentrator. The main shaft is down 150 ft., and the adit at the 75-ft. level is in over 700 ft. on the main vein by the northwesterly. In the opposite direction driving has been extended for 350 ft., and a good deal of stoping done. No. 2 vein, 200 ft. north, is being worked by a cross-cut from No. 1, and 200 ft. of driving has been done on it, and ore extracted assaying 4000 oz. silver per ton. At No. 3 shaft, 1000 ft. southwest of the main shaft, a 12-drill compressor and two 100-hp. boilers have been installed, and a hoist is being put in. At the Coninagas there are 10 stamps and three concentrators in operation, with a four-stamp and one concentrator under construction, with a four-stamp and two concentrators under construction. They were manufactured by Chalmers & Williams, each stamp weighing 125 lb. A nugget of almost pure silver weighing about 100 lb. was found on the 75-ft. level this week. Three veins running from the Nipissing have been discovered on the eastern boundary of Coninagas. The new shaft on the Temiskaming property is down 90 ft. A 20-drill Cecils tandem compressor has been ordered from the Stillwater Machinery Co., of Chicago, and a new hoist and additional boilers will also he put in. The O'Brien mine recently struck a new vein 5 in. wide, yielding 2800 oz. silver per ton. No. 5 shaft of the Silver Leaf is now 204 ft. down, and driving at the 75 and 155-ft. levels is going ahead. The main vein shows up throughout the shaft, and at the bottom is 5 in. wide, consisting of calcite and silver. A stranger encountered 15 ft. below the 125-ft. level was followed and good ore obtained. A cross-cut at the same depth also struck a 6-in. calcite vein which was driven on for 137 ft. and found to have good silver content. The Right of Way has found additional orebodies, including a 4-in. cross-vein, struck in driving at the 70-ft. level, yielding 4000 oz. silver per ton. A valuable discovery has been made at the Victoria mine in a shallow deposit 100 ft. from No. 5 shaft, consisting of 5½-in. calcite stringers running parallel, ranging from 1½ to 2 in. wide, carrying native silver. Active operations are being resumed on the Peterson Lake property, where a shaft is being put down on a salena vein recently discovered. A surface force of 20 men is engaged in prospecting and development. The La Rose Consolidated has declared a dividend of 2½c. for the quarter ending August 31. The Red Rock Mining Co., at a meeting held here on September 8, decided to go into liquidation, having debts of $10,000 which cannot be met. The Company is capitalized at $1,000,000, and the shares have all been issued.

The O'Shea property of 40 acres, situated in the Temagami Reserve, six miles west of Elk City, has been sold to E. D. Warren & Co. The outcrop of silver, consisting of decomposed ore filled with silver nuggets, has been marked for 2000 ft. on this property and land adjoining. Development will be begun at once by a force of 25 men, in charge of R. Longley.

**Butte, Montana.**

**Butte Central & Boston Bankruptcy Proceedings.** — Development of Alex Scott Mine.—Deepest Shaft in Butte.

A trustee in bankruptcy has been appointed for the Butte Central & Boston copper corporation, and an effort will be made to re-organize. The company started about a year and a half ago with great promises, backed by capitalists in
The company is being prepared at Butte. The Ophir is generally considered to be capable of developing into a good mine, under proper management, and it is likely that a re-organized company may succeed.

The Alex Scott mine, of the Butte-Montana Mining Co., is again under development. Eastern men have secured control and have made the first payment of $10,000 on a majority of the individual and treasury stock. The company owns two claims, the Alex Scott and the Amiee, the former being situated next to the West Colusa, one of the Amaiganated's big producers, with which it is connected at the 900, 1600, and 1200-ft. levels. These openings were made by the Butte & Montana Co. for the ventilation of the West Colusa. That company, in consideration of permission to make the connections, sank the Alex Scott shaft several hundred feet, and it is now down to the 1200-ft. level, the Boston & Montana Co. spending about $65,000 on the work. Nine levels have been opened. By arrangement with the Boston & Montana the Alex Scott has been developed at little cost to the Butte-Montana Co. The shaft has two compartments down to the 900-ft. station, and three compartments below that point. Commercial ore has been found on the 600, 900, 1000, and 1200-ft. levels, and preparations are being made to open them for mining. The Alex Scott, although having a surface area of only five acres, is surrounded by producing mines. The West Colusa lies south of it, the Leonard mine of the Boston & Montana to the east, the Moc to the north, and the Sunny Side to the west. The Alex Scott has a larger surface area than the famous Minnie Healer mine of the Butte Coalition Co., in the same portion of the Butte district, which has been valued at $10,000,000. The Butte-Montana is capitalized for $1,000,000, in a million shares at $1 par. The Little Arnie is a silver property with a surface of 20 acres, situated in the northern part of the Butte district. The officers of the company are: T. N. Barnsall, of Pittsburg, president; J. P. Brown, of Butte, vice-president; W. H. Lindsay, of Butte, secretary and treasurer.

The deepest shaft in the Butte district is that at the High Ore mine of the Anaconda Co., which is down 2900 ft. The lowest level is also in that mine, at the 2900, the deepest point at which mining is being done.
field in the Koelvaunobly ranges, but results have been disappointing. Save for a little work being done by the original prospectors, the place is deserted. A prospecting party that had set out with good intentions, recently returned to Perth and disbanded. Coupled with these disappointments, it is announced that the Associated Northern mine is to reduce its output to about $30,000 monthly; the Great Fingall is also reducing its yield from $175,000 probably to $100,000 monthly; and the Lancefield mine is shut down for some months to overhaul the plant. The gold yield of the State will suffer a great deal in consequence, and there is little or nothing to make up for the deficiency. A good many accidents have occurred of late, mainly through falling rock. In most cases these are purely accidental, but loss of life is recorded in nearly every instance.

One of the residue heaps of the Oroya-Brownhill Co. contains 750,000 tons of slime from the treatment of sulphide-telluride ore, by wet crushing and cyanide. This is now being thoroughly sampled by boring and driving a tunnel through the heap. A Cassell plant is being worked on another lease nearby, and trials are being made on parcels from the dump, with a view to erecting a large plant on the Cassell lines. Metallurgically, there is little or nothing fresh from this centre, excepting a rather interesting case recently brought out in the Supreme Court in Perth. The facts were these: The Ivanhoe mine management has always stuck to the raw treatment of its ore, and the extraction has never been high, that for 1907, according to annual report, being 87%. The equipment consists of Gates crushers, 100 stamps of 1200 lb. weight, copper plates, classifiers for rough classification prior to concentrating on Wilfley tables, Wheeler grinding pans, another set of Wilfley, the pulp from these going to the collecting vats, where the sand is caught and given a double treatment with cyanide. The slime overflows from the above vats and is run into settlers, pumped into agitators, treated with bromo-cyanide, and finally filtered-pressed. The concentrate from the Wilfley is roasted in Edwards tilting furnaces, ground in pans, agitated with cyanide and filter-pressed. This treatment has been adhered to for many years, and not being satisfied with the above extraction, the management borrowed or contracted with E. S. King, of the Oroya-Brownhill mine, to try and improve the extraction of the Ivanhoe. The treatment followed in the Brownhill mill is: Blake crushers, 50 heavy fast-running stamps, no plate amalgamation, rough classification before the coarse sand runs to Wheeler grinding pans, another set of Wilfley, the pulp from these going to the collecting vats, where the sand is caught and given a double treatment with cyanide. The slime from all parts is run into \( V \)-shaped settlers and thickened, then into agitating vats, treated with bromo-cyanide, and finally filtered-pressed. As in the Ivanhoe, the concentrate at the Brownhill is roasted, in this case in Merton extended furnaces, ground in pans, agitated with cyanide, and filter-pressed. The extraction with this treatment is 94%. The ores in both cases are similar. Bewick, Moreing & Co. are general managers of the Oroya-Brownhill and consulting engineers to the Ivanhoe Co. After the Brownhill metallurgist had done certain work at the Ivanhoe, saving, as he reckoned some $290,000, he demanded his fee. None was forthcoming, as a result, he expressed to the Ivanhoe Co. for $25,000 for services. For the defence, it was stated that the imported metallurgist had done little or no good, that he was borrowed from the Brownhill, which, as before stated, is run by B. M. & Co., that another Brownhill man had done most of the work, that no contract was made, and that the Brownhill treatment to some extent had simply been applied to the Ivanhoe. Several well known Brownhill men testified that they considered that the Brownhill man had done very little, at any rate, $500 was sufficient remuneration. However, in summing up, the Judge said the whole case rested on whether or not a contract had been made. The Ivanhoe management declared that the Brownhill man was there as a servant of the firm of Bewick, Moreing & Co., while the plaintiff said he was there in his private capacity. A great deal of contradiction was apparent on all points. The Judge remarked that "these business men, as they called themselves, did business in a most unbusinesslike manner." The instructions had been cast on the plaintiff, and the Judge said the Judge, "If a man were a fool he might be privileged to write the alphabet backward and forward after his name, and yet remain a fool. Conversely, if a man were naturally clever in his profession, it mattered little whether he had or had not behind him a certain diploma." It may be explained here that several of the witnesses were the defense for the company; A. R. S., in his letters after their names, while the plaintiff had not. To conclude, the six jurymen decided that a contract had been made, and was carried out by plaintiff. Damages of $15,000, with costs, were awarded to Mr. King.

J. W. Sutherland, manager of the Horshoe, has gone to England, by way of India, on three months' leave. Mr. Loring, of Bewick, Moreing & Co., has returned from England by way of Burma. The July yield from "the State was valued at $2,900,000; dividends being $1,950,000. The production from the principal mines in July was as given below, all returns being low on account of the fuel strike, and the costs in most cases unusually high.

*Loss.

MANILA, P. I.

The greatest mining success in the Philippines today is the Paracale Gold Dredging Co. with an output of about $1400 per diem from less than 400 yd. of dirt handled. On the strength of this the Philippine Gold Dredging Co. has just been organized under the laws of the Philippines, with a capital of $200,000, divided into 20,000 shares. Half of this was paid for about 400 acres of land adjoining the Paracale Gold Dredging Co.'s property, where the dredge is now operating. Seven thousand five hundred shares have been sold at par, and the resulting $75,000 used to buy the dredge. This leaves $25,000 worth of stock in the treasury for emergencies. This stock was all subscribed in two days by Manila business men.

A second hand Rindsay 3½ cu. ft. bucket dredge, which was on the island of Masbate, has been purchased and is now being dismantled for shipment to Paracale. The dredger will be brought to Manila and have a 25-ft. piece set in, as tests show the ground to be 50 ft. to bedrock in places. It is estimated that this dredge will be made ready for digging at a total outlay of not to exceed $50,000, including all new property besides the original. The first net return is to go to the stockholders subscribing the $75,000; after this all share alike.

The Paracale district takes in all of the territory north of the Lobo river, and as far west as the east coast of
Mambulao bay, and is situated in the northern part of the province of Ambos Camarines on the eastern coast of the island of Luzon, P. I. It is reached by steamer from Manila around the southern end of Luzon, and through the Sorob Bernardino rail. Mercedes, the port of call for them is the nearest point at which steamers regularly call at present, which is a four days' trip from Manila. Most of the mining has been, and is now being, done in the northern part of the district, about 5 miles wide and 10 long, easttary and westtary, with Paracale in the eastern end on the coast, and Mambulao in the western, on the bay. Paracale, lying westerly from Mercedes about twenty miles, is reached by sail-boat, or over an exceedingly bad trail by way of Indian, also in the same district. There are no roads, and even fair trails are unknown in this part of the province.

Streams draining this low hilly country flow in all directions except due south, and the rise and fall of the tide, which is about 5 ft., affects them nearly to their source, making water transportation easy. The Labo and Malaguít rivers, running easterly, are the principal ones, and with their tributaries drain most of the country. Mambulao bay, and the mouth of the Malaguít river, furnish good anchorages. Mount Barcay, in the southeastern portion of the district, is about 3000 ft. high, but shows no mineralization. May Cruz mountain, forming Mambulao point, in the northwest portion of the district, is somewhat over 1000 ft. high. On the southern flank is the old San Mauricio mine. The Anchor adit at Mambulao, with its supposed miles of workings, is thought to run under this mountain.

The remainder of the country is quite flat, with low hills and ridges dividing the tide-water streams. These hills and ridges, except where cleared by the natives for growing hemp, are covered with heavy timber and a dense undergrowth, much of which is armed with spines and hooks. Owing to the frequent heavy showers throughout the dry season the country never gets burned off like Benguet or Masbate, so that prospecting is quite difficult. The country is inhabited by Tagalogs, though there are still a few Bicolos left. Occasionally Negritos from the interior mountains are found at work on the small farms, where the chief industry is hemp growing. The rainy season occurs opposite to that at Manila, the heaviest precipitation occurring during December, January, and February, caused by the northeast monsoon.

Geologically the country is mostly hornblende, diorite, scoria at places. These are cut by porphyry dikes, usually of the more acid types. The vein systems run northeast and southwest, and stand nearly vertically. The ores are usually white quartz, filled with much pyrite and a little chalcopyrite and galena, and possibly sphalerite and pyrrhotite. The veins mostly follow "contacts," in which case there are usually parallel veins in the country. Most of the veins are too small and pockety to pay except as worked by the natives, who place no value on their time. Concentrated by erosion, they have made wonderfully rich placer ground. Gold has been mined here for several hundred years, and many of the main veins of the district can be traced for miles by these old workings, the most of which are caved in. The Anchor adit at Mambulao, now caved, was re-opened by the Philippine Mineral Syndicate for about 1700 ft. The insurrection of 1909 stopped this work, and the veins and workings were reached. No native now living has ever been in these workings, but tradition tells of miles of workings. Tradition also explains the ruins of the old fort on the hill above the mouth of this adit as a protection against the Moro pirates from Mindanao. Government records show an annual output of about $300,000 in the seventeenth century. It is said that Mambulao was then the second city in the island, with a population of 50,000. The natives could work only to a little below water-level. The placer-work was confined to panning and arrastre-work. In 1894 the Spanish Government prohibited mining by natives, and commenced granting concessions to Europeans. A British company, the Philippine Mineral Syndicate, acquired property throughout the district, and have spent upward of 600,000 pesos. Two mills were erected. Work had hardly started when the insurrection broke out. A large amount of money was also spent by the Sociedad Minera La Honancita, another English company. The only large mining of importance, attempted since 1896, is that recently started to re-open the San Mauricio on May Cruz mountain, the Tumbaga shaft, 3 miles south of Mambulao, and the San Antonio adit, across the Paracale river from the town of Paracale. These all belonged to the Philippine Mineral Syndicate. The San Mauricio was badly caved, but now practically all its workings are accessible. The Tumbaga shaft was found to be only caved to a little below water-level. It is now being pumped out, while the mill is being put in readiness for crushing. The Paracale Gold Dredging Co., Ltd., a New Zealand corpora-
mill. Dredging was started within 500 ft. of the sea. Considerable difficulty is experienced by a layer of black sticky mud that balls up in the screen. Over 90% of the dirt screens the screen with 1/4-in. holes. The largest nugget so far recovered weighed about 2 3/4 ounces.

A Mr. Wilson has under option over 3000 acres, taking in nearly all of Malaguit river. There is a testing outfit on the ground and another expected soon. Should gold be found in paying quantities it will be the greatest Co. of placer ground in outlying districts still unprospected. The bottom, on which the gold gravel rests, as shown by the dredge, and also by tests in Malaguit river, is ideal, being a soft decomposed granite. A dredge for this country should be fitted with an extra boom or two to handle the mine stamps.

Inter-island steamers can come within a few miles of any of the properties, and freight unloaded into 'bancas' can be conducted to nearly all of them. There is an abundance of timber for mining operations. Whip-sawed lumber costs on the ground at the rate of 50 centavos for a cut 12 in. wide and 15 ft. long. Mangrove swamps follow tide-water far into interior. This wood makes fine fuel, and can easily be gotten out in 'bancas' and costs delivered 4.50 pesos per cord. Natives can receive 90 centavos to 1 peso per day and furnish their own 'chow.' More pay is given on the dredge, as the men become somewhat skilled. Small surface tunnels can be contracted for at 50 centavos per foot.

**MEXICO.**

**Meeting of Congress. — Review by President. — Silent Concerning Mining Laws. — Railroad Rates on Ore and Fuel. — Domestic Coke.**

The 24th Congress of the Mexican Republic convened in Mexico City on the evening of September 16, and President Diaz read his annual message to the assembled legislators, the ministers of the cabinet, and an interested public. The message was a lengthy review of the country's condition, but it was sparsely sprinkled with suggestions or recommendations of any nature to the Congress, and was almost wholly lacking of interest to the mining fraternity in general.

The President stated that the general map of the Republic was progressing rapidly, and that in addition to the work of the Geodetic Survey, the several States were aiding the Federal Government in the completion of this important undertaking; he reported that the total amount of silver and gold coined issued under the new coinage law now amounted to $122,000,000; and he called attention to the fact that in the six months under review (January to June) 5600 mining titles had been issued, covering 58,781 pertenencias, or 141,000 acres, as compared with 61,000 pertenencias, or 147,400 acres, for the preceding six months. The message recalled the necessity of aiding the State and mines of Sonora in escaping with the slag. A Co., a concession for the free importation of fuel-oil for a period of years, or until such time as it can be supplied with native oil, in order that operating expenses might be cut to a minimum, and the wisdom of granting the concession seemed to be shown in the great impetus given to mining throughout the State of Sonora immediately upon the resumption of operations at Canso. In closing, General Diaz said that in spite of the crisis, for which neither the country nor the administration was in any way to blame, affairs had progressed well, and that with peace "we may trust that the prosperity of the Republic will endure and wax greater as the years go by." Whatever inference may be drawn from the fact, it cannot fail to be noted that the President's message, more than the Congress, is to install laws which have caused such widespread discussion, nor to the new rates on ores, coal, and coke that are now before the railroad commission. So thorough was the President's review of the country's affairs that his silence on a subject affecting the Republic's most important enterprises could not have been unintentional, and the omission is certainly to be regretted. The mining men of the Republic, however, have not failed to give the subject full consideration, and while they obtained but a rather poor compromise on the question of ore rates, as explained in my former letters, every possible pressure is now being brought to bear on the railroad commission to prevent the admission of the proposed new rates on imported coal and coke. A good impression of the present rates and the proposed increases from the port of Tampico, the main port of entry for these materials, is afforded by the following table:

<table>
<thead>
<tr>
<th>Coke, Proposed</th>

In other States the railroads make the usual cry that they are now handling this business at a loss, but it would appear that they have been a long time finding it out. The mining men are the strongest in their objections, for as the smelters are the largest consumers of coal and coke, an increase in the freight will necessitate an increase in smelting charges, which means again that the miner "must pay the freight." Virgin coal and coke is now being delivered at Tampico for $6.20 and $3.05 per ton, respectively. The domestic product is slightly lower in the matter of coal, and slightly higher for coke. But the supply of domestic coal and coke is insufficient and the quality poor. An average record covering a period of several years gives the following:

<table>
<thead>
<tr>
<th>COKE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Water</td>
</tr>
<tr>
<td>Domestic</td>
</tr>
<tr>
<td>Foreign</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>ASH</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
</tbody>
</table>

From this anyone familiar with metallurgical problems can infer that the high percentage of ash in the domestic products, and the higher silica and lower lime and iron in the ash, means the expense of purchasing additional lime and iron, with the consequent increase in the amount of slag made by the furnace and a greater loss in precious materials. There are the best of reasons, therefore, why the smelters demand foreign coal and coke, so that the increase in freight of roughly 82 per ton means, for a 1000-ton plant, using from 12 to 14% coke on the charge, approximately $250 per day added to its running expenses, which, with the extra charges on the coal also, would amount to over $100,000 per year. The combined extra expenses of the smelters alone in Mexico would be at least $1,000,000 annually, to which must be added that for mines and mills, another million pesos, all of which the miners must pay.
Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Native bismuth, in crystalline form, exists in the alluvial deposits of the Sinuk and Cripple River placer of the Seward Peninsula, Alaska.

Colemanite (the hydrous borate of lime) has been found in large quantity in the Soledad canyon, near Newhall, in Los Angeles county, California.

Scheelite (tungstate of lime), a heavy, opaque, white mineral, is found in the placer of the Nome region, and collects with the gold in the sluice-boxes.

Aluminum sulphate is produced in such large quantities, and so cheaply, that only under exceptional circumstances could a new competitor enter the field. There is no market whatever for alunite at the present time.

Native copper, cuprite, and chalcocite, all of which are the result of secondary enrichment, are found in a big vein of rhodochosite (manganese carbonate) in the Tubal Cain mines, situated in the Olympic range, Washington. In depth the secondary minerals give place to copper pyrite.

Antimony is at the moment in small demand, and although quoted at 80c. per unit (that is, for each 20 lb.), at Atlantic tide-water, and 25c. per unit at San Francisco on ore free from arsenic and containing not less than 50% metallic antimony, an unexpected earload of ore would overstock the market. It is used in making type-metal, soft alloys where expansion in setting is required, and in alloys used for anti-friction metal.

Talc is a product of alteration from pyroxene, amphibole, muscovite, and similar magmatic minerals. Its composition is \( \text{H}_2\text{Mg}_4\text{Si}_8\text{O}_{16} \). It is used for paper making, for linings in stoves, hearths, sinks, and also, ground and moulded, as gas-tips. It is used to give a finish to blackboards, and it also gives a flue texture to tinted plastering. It is also employed as tailor's chalk, as a lubricant, and as a dressing for leather.

Bismuth in ore may be determined as follows: The ore is decomposed with \( \text{HNO}_3 \), and evaporated to fumes with dilute \( \text{H}_2\text{SO}_4 \), the residue filtered off and treated again with \( \text{HNO}_3 \), diluted, and filtered. The filtrates are combined, and the bismuth is precipitated with \( \text{H}_2\text{S} \), filtered, and washed. The bismuth sulphide is dissolved in \( \text{HNO}_3 \), and the solution is exactly neutralized with \( \text{NH}_2\text{OH} \), using methyl orange as an indicator, and then acidified with one or two drops of 30% \( \text{HNO}_3 \). A large excess of ammonium molybdate is added, and the solution is heated gently until the precipitate collects. It is then filtered and washed with a 3% \( \text{(NH}_4)_2\text{SO}_4 \) solution. The precipitate is dissolved in \( \text{H}_2\text{SO}_4 \), passed through a column of zinc (Jones reducer) with suction, and titrated with potassium permanganate.

Specific gravity of cement is a good simple test of the thoroughness of its burning. The specific gravity is determined by immersing a known weight of the cement in a liquid which will not act upon it (usually turpentine or benzine), and obtaining the volume of the liquid displaced. The specific gravity is equal to the weight of the cement (in grams) divided by the displaced volume (in cubic centimetres). The specific gravity of portland cement varies from 3.05 to 3.25, and natural cement between 2.80 and 3.00. The specific gravity of cement decreases with age, owing to the absorption of water and carbonic acid from the air.

Manganese is a common associate of gold and silver ores in many parts of the world. Usually it represents conditions of deposition from solution at no great distance from the surface. This, of course, applies only to cases where manganese is present in notable amounts, for it is seldom entirely absent from any vein. It occurs quite commonly as the pink carbonate, rhodochrosite, and is quite characteristic of the veins in the Telluride district, Colorado. Usually, however, it is crystallized with calcite and ferric carbonate, and later it is released, forming accumulations of black material resembling wad. Where this occurs excessive leaching has generally taken place.

Barite is used to a large extent as an adulterant for white paint. It has a certain advantage as such, because of its absolute unalterableness under ordinary atmospheric conditions. White lead will take up sulphur from the atmosphere of cities, forming lead sulphide, which, being black, gives to the paint a dirty tinge. The barite, however, will remain pure white. As found in nature it usually contains iron, which is leached out from the finely ground product by sulphuric acid, aided by steam. A very fine grade of venetian red pigment is recovered from the leachings. The disadvantage of barite in paint is that it does not mix with the oil as well as white lead, remaining granular, no matter how finely it may be ground.

Coal washing involves the exact reverse of metalliferous mineral concentration. The heavy particles in coal are the deleterious substances which are to be rejected, namely, the slate, pyrite, and 'bone coal.' There is a great variety of appliances used, but the larger amount of coal washing is done with jigs, which are of large capacity and treat the coal at a cost varying from 2½ to 7 cents per ton, according to local prices of labor and supplies. Slate can be more completely eliminated than sulphur, because the latter is present not only as pyrite, but as 'organic' sulphur, that is, combined with the substance of the coal itself. Also pyrite is present to some extent in the form of thin films, called 'scale sulphur,' which remains between the cleavage planes of the coal, and even when broken free will float off with the coal.
Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

Forest Reserve Administration.

The Editor:

Sir—The Forest Reserve has been discussed from time to time in your columns, by geologists, mining engineers, theorists, and lately by the paid employees of the Interior Department itself. The writer, who owns mining property and has been engaged in mining within a forest reserve for the last six years, believes that there are those who would like to know how these theories work out in actual practice on the ground, and how the prospector, the mine-owner, and the home-seeker, are actually affected by this policy, as at present administered.

In the first place, the large corporation appears to have no trouble in Alaska in securing the elimination from a forest reserve of any tract desired. In fact, the relation of these corporations with the Bureau seems to be always smooth and satisfactory. I cannot at this time enlighten your readers as to just how this is accomplished. With the smaller corporation, or individual of limited means, it is different. He must conduct his business, to a great extent, through permission, granted or refused, extended or revoked, according to the momentary pleasure, whim, or fancy of some officer of this Bureau. If, for instance, you wish, within the limits of your claim or elsewhere, to conduct a general merchandise store, for the purpose of supplying a mining camp, and the prospectors and others in the surrounding country, with merchandise, you must first get permission from some officer of the Bureau. The officer can refuse permission altogether if he wants to; or he can require you to furnish bonds of any character and in any amount he may wish. The officer may tax you any amount of money per year he may choose, for letting you conduct your store. Any agreement made between yourself and the officer is binding upon you, but not on the officer or the Bureau, for at any time your permit may be revoked, and you must then step out and leave your improvements, if the officer wishes you to. In short, when you have secured his permission, paid his price, put up your bonds, made your improvements, and put in your stock, you have not that assurance that you will be allowed to conduct your business which would ordinarily be given the victim in a case of private blackmail. This applies to the ‘home-seeker’ who is so tenderly coddled in the ‘Use Book’; it applies to the miner who has to carry his ores across Government land to reach a market; it applies to the prospector who may want to put up a little cabin in which to winter; it applies to anyone who may want to put out a little garden to raise a few vegetables for his own use. The policy is proving to be an industrial blight upon this part of Alaska.

The writer, having implicit confidence in the ‘Square Deal,’ made a personal appeal to President Roosevelt. The appeal was duly acknowledged, and the result was as follows: an employee of the Bureau was sent from Washington. It was his first trip to Alaska. He immediately began using the local paper and his own tongue, in an effort to offset or to overcome any adverse criticism of the Forest Service. It appears that to each one who went to him with complaints, he expressed genuine surprise, and informed the plaintiff, ‘Why, you are about the only one who is at all dissatisfied.’” Whence he was seemingly overwhelmed with the wrongs which had been done to various parties, and the harm which must result from such despotic authority in the hands of petty employees of a Bureau, he would emerge from the dilemma smiling and confident, with a phrase he seemed to have learned at some one’s knee back in Washington. It was this, “So I understand that your troubles, aside from so and so, and so and so,” (naming them) “are anticipated rather than real.” This was the result of the appeal to the President, and we were forced to conclude that here was a sample of the ‘Square Deal’ in action. If your readers will study the ‘Use Book’ and imagine themselves living under the conditions provided therein, they can hardly fail to discover that some considerable space has been devoted to deceit and hypocrisy in this public document. It would seem that the purpose has been to conceal from the general public the discrepancy between the Administration’s policy and the policies for which a Republic is supposed to stand; or, in other words, to sugar-coat a pill of despotism for the American people.

Another document was issued by the Administration, June 14, 1907, entitled, ‘The Use of the National Forests’ (meaning the forest reserves only). Taking page 8 as a sample, we read, “Now, before new forests or additions to old ones are made, all the lands are examined on the ground. The greatest care is used in this work. Every section of land is examined, mapped, and described, and the boundaries are drawn to exclude, as far as possible, everything which does not properly belong in a National Forest. Two very detailed maps are made. One shows just what is growing on the land, the other shows who owns or claims the land. Every bit of cultivated land is located and mapped, as well as the land which is suited to cultivation but which is not cultivated at present.”

After this was published, the Tongass Forest Reserve was created. It is situated in a largely unexplored region along the coast range. In a general way it consists of a fringe of timber-covered foothills, fronting upon an arm of the Pacific Ocean and backed by precipitous snow-clad mountains. In this instance (No. 1), “All the lands” were not “examined on the ground.” (No. 2) “Every section of land” was not examined. (No. 3) “Every section of land” was not mapped. (No. 4) “Every section of land” was not described. The land has never been sectionized at all. (No. 5) “The boundaries” were not “drawn to exclude as far as possible every thing which does not properly belong in a National Forest” (meaning Forest Reserve). (No. 6) “Two very detailed maps” could not be made. There were no data with which to make such “very detailed
maps," and there aren't yet. (No. 7) "One" does not "show just what is growing on the land." (No. 8) The land suited to cultivation is not "located and mapped." And this is only page eight.

Another Forest Reserve was created about the date of this publication at the head of Prince William sound, out of a likewise mountainous, unsurveyed, and largely unexplored country, and the statements are equally false if applied to the archipelago Forest Reserve of southeastern Alaska. Many other falsehoods, half truths, and misrepresentations are contained in this book, and may be found by those who will go over it in connection with the "Use Book."

About the time of the publication of this volume of 'romantic fiction' the President made an attack upon what he termed 'Nature Fakirs.' What a pity he failed to find the 'Bigger Game' nearer home while he was in the mood. The killing would have heartened up the 'Square Deal' which used to be such a popular pet. The Nature Fakirs did not use the people's money to print their romances; they were not the paid servants of the people when they wrote their fiction; they were not abusing the confidence and trust of the voters to foist upon the country a form and policy of bureaucracy contrary to the first principles of a Republic.

The miner is willing to pay for timber off Government land, but he objects to being made dependent upon the momentary pleasure, whim, or fancy of some 'sub' of this Bureau, for his timber or for anything else. The prospector is willing to pay the Government for the right to make himself a home, but he is not apt to build a home where his title rests upon the momentary pleasure, whim, or fancy of some 'sub' of a Bureau. The Act of June 11, 1906, was intended to open the Forest Reserve to the home-seeker; but the rights were all conferred upon the Bureau and none upon the home-seeker. So it is really the Bureau's 'sub' in the field to whom the home-seeker must go, and upon whose momentary pleasure, whim, or fancy he must depend for a home within a Forest Reserve. In at least one instance, however, the Bureau's 'sub' proved himself a friend of the home-seeker. About two miles from here an old Indian had cleared a tract of land and made a garden. A 'home-seeker' came along, wanted the old Indian's garden, and by inducing the Bureau's 'sub' to exercise his rare discretionary powers, he got it, in spite of the old Indian's protest. Of course, there was neither justice nor common sense in such a proceeding; but by experience we have learned not to expect justice or common sense, nor even the truth, from a 'sub' of this Bureaucracy; the literature furnished them can hardly be expected to promote truthfulness.

On this Forest Reserve foolish officiousness, financial injury, favoritism, injustice, ignorance, official swagger, and insolence, have all been perpetrated by hirelings of this Bureau upon the people who by their toil and industry are breathing the first breath of industrial life into this 'Silent Land.' The people of Alaska want their timber preserved for the development of Alaska's resources; and until the Forest Reserve was created no timber could be shipped off Government lands, out of Alaska. Under the Forest Reserve, however, "Timber cut from any National Forest" (meaning Forest Reserve) "may be sold in any market anywhere." (Reg. 29, 'Use Book', 1907.) Now see page 61 of this same 'Use Book': "There is no limit but the capacity of the forest to the quantity which may be sold to one purchaser, except that monopoly to the disadvantage of other users of forest products will not be tolerated." How glad we should be that under any stress of circumstances, this Bureaucracy will decide what is to our advantage or disadvantage in this little matter of monopoly of our timber. The plain truth is that this Bureaucracy, since the creation of the Forest Reserve, can do just as it likes with our timber. It has the authority to let any monopoly skin the land, at any price, in spite of the protests of the people. No falsehood or misrepresentation contained in the literature of this Bureau is more complete or pernicious than the idea industriously and adroitly spread that those who are opposed to the present policy have selfish designs upon the public domain, or are opposed to the protection of the public domain from waste and monopoly. To the spreading of this false idea the Bureau owes much of its success in Congress; it seems to be their greatest weapon; and it has been successfully used to stop the ears of the public to the protestations of the victims.

This Administration, in the promulgation of a public land policy, had the advantage of public confidence, public sentiment, ample means, and lavish authority bestowed by Congress; and the result is this policy—despotism, graft-breeding, satured with deceit, and unbefitting a Republic. If this seem harsh, turn to page 10 of the book issued by the Bureau, and entitled 'The Use of the National Forests' (meaning Forest Reserves). There we read, "Congress has extended the homestead law, slightly modified, to the National Forests." In Alaska the homestead law outside of Forest Reserves allows three hundred and twenty acres; within a Forest Reserve, one hundred and sixty acres only. Is it truth or falsehood to say it is "slightly modified"? In securing a homestead outside a Forest Reserve, the home-seeker's rights are defined by law and precedent; there is no personal favoritism about it. Within a Forest Reserve he can initiate no title, and secure no home, except through the personal favoritism of some member of this Bureaucracy. Further on, same page, we read, "A National Forest, then, does not in the least shut out real settlement. It encourages it." Is this truth, or deception? Would you prefer to make your home under the conditions provided in the 'Use Book', and become subject to the momentary pleasure, whim, or fancy of some 'sub' of this Bureaucracy, or on free land where your rights were defined by law? What is the significance of over three hundred thousand American farmers renouncing their allegiance and going to Canada for homes? Speaking of timber, page 12 reads, "There is no chance for monopoly, because the Secretary of Agriculture must by law sell as much or as little as he thinks best. To whom and at
whatever price he thinks will best serve the interests of all the people." Quite extraordinary, don't you know, and so simple. If only the Constitution were out of the way, he might run the whole Government. "But suppose he should make a mistake!" But he wouldn't, you know; and even if he should, he wouldn't mean to; he is a fine fellow!

But we were looking for deception. There is no such law as stated on page 12 in the above quotation. There never was. Picture to yourself, our senators and representatives enacting and the President signing a law to compel a member of the Cabinet to do just as he pleased. Now the fact is, the law does not say that the "Secretary of Agriculture must"; the law is not mandatory at all in this particular, but it makes our official romance more effective and plausible to say that the "Secretary of Agriculture must". In the 'Use Book' for 1907 geologists and engineers may get some new ideas in regard to the examination of a mineral claim. Read pages 36, 37, and 38. Imagine, if you can, a 'sub' of this Bureau swollen with despotic authority, furnished with these instructions, and even more ignorant of such matters than the person who wrote them! You, who are geologists, engineers, or practical miners, how would you like to have to depend for patent upon the recommendation of such as this? This is precisely the condition which confronts us, and yet "Prospecting and mining are absolutely unchecked." (page 11). "If he wants to get patent to any of them he can do so," and "a National Forest does not affect this work in the least," (page 11). "Do not use the land of an unpatented claim for improvement or construction work which does not tend to the actual development of the claim, consistent with its character, until you have secured a permit from the Supervisor," (page 28). These quotations are all from the book before-mentioned, and entitled 'The Use of the National Forests,' (meaning Forest Reserves).

Finally, even the very title of this book is a deception. The Bureau has no jurisdiction under the law, over any portion of the National Forests, until the President proclaims, "... that there are hereby reserved from settlement, entry, or sale, and set apart as a public reservation ... " The people were not altogether satisfied with the reservation policy of this Administration; so it would seem that in order to overcome the rising tide of discontent it was thought best to give the Forest Reserve an alias, to save its neck. Instead of coining a new name, as is the custom with those who use an alias, it was called 'National Forest'; and now it can no longer be distinguished by name at least, from that part of the timbered public domain, which has not yet been, "... reserved from settlement, entry, or sale, and set apart as a public reservation ... " And furthermore, 'it will escape some of the criticism and scrutiny it would receive if called by its right name.' Here then, is the policy as viewed from within. Stripped of its cloak of hypocrisy and deceit, deprived of its alias; standing before us in its right name; here is the Forest Reserve as an actuality, not as an ideal or as a theory. Here is where the ideal and the 'Square Deal' fail to track, and here is where truth and righteousness, loyal citizenship, and quickening industrial life, are bludgeoned to death at the altar of despotism. Both the forests and the land should be protected from waste and monopoly. There should be Forest Reserves wherever common sense and modern science indicate their necessity; and if they are administered in harmony with a representative form of government, even the most timid need not fear to call them by their right name. All our timber is not worth the price the common people paid for this Republic, and it is not fitting that there should be taint of despotism or trace of paternalism in the administration of the public domain.

Ulysses S. Rush.

Foothill Copper Belt of the Sierra Nevada.

The Editor:

Sir—I have read with much interest the various letters published descriptive of the copper belt of the foothills, and have gathered much information from them. It seems to me, however, that Mr. Hershey, in his letter published in the MINING AND SCIENTIFIC PRESS of September 5, goes quite too far in trying to make out that another type of deposit than those instance by previous writers is to be found there. I have a fairly good knowledge of those mines, and I must state that I have never found chalcocite in any such quantity as would constitute a separate type of deposit. In fact, I have never seen undoubted chalcocite in any of the copper-belt mines. There is, to be sure, a small quantity, rising to a few hundred pounds in some places, of an impure and partially decomposed sulphide, which may as well be called chalcocite as anything else, although as a matter of fact it is quite as close to zinc-blende as it is to any typical mineral. Mr. Hershey’s conclusions as to the value of the deposits seem to be the same as those at which Lang, Reid, and others have arrived. Consequently the mineralogical character of the copper-bearing minerals is more or less academic. It matters little whether the metal is contained in the ore as chalcocite, as chalcopyrite, or as an oxidized substance, provided that the copper content is there. The portion of the veins or lodes in which any secondarily enriched ore could exist is very limited, not being more than a few feet vertically in any of the mines, and in consequence we do not find extensive deposits of such ores. There often is found in certain parts of the field a dark soft mineral which in certain parts of the field a dark soft mineral which possesses somewhat the characteristic of chalcocite, but which when tested is found to consist mainly of blende in a state of partial decomposition. Considerable of this is found in several of the southern properties, and at first sight may be taken for a copper mineral, especially chalcocite. I am inclined to believe that Mr. Hershey may have been misled in this particular. The discussion on the copper-belt mines is proving interesting and valuable, but I may suggest it tends to go too much into minutiae. What we want is a statement of economic conditions, and not an essay on mineralogy.

S. W. Benjamin.

San Francisco, September 9.
LA GRANGE HYDRAULIC MINE.

Written for the Mining and Scientific Press
By Donald F. Campbell.

The La Grange, the largest hydraulic mine in active operation, is situated in the centre of Trinity county, California, at the southern extremity of Bally Mtn., a range rising to an elevation of 7625 ft. From the divide at the penstock above the mine, the Trinity river is seen three miles to the west at the foot of Oregon guleh, now filled with débris, resembling the terminal moraine of some great glacier, while four miles to the east is Weaverville, the county seat. On the north and west, Trinity county is hemmed in by mountains, and two wagon-roads are the only means of access. There is no wagon-road communication with the Pacific coast, although Humboldt bay is only 33 miles west of the county.

The principal railway supply-point is Redding, and a daily stage makes the trip of 52 miles in 12 hr. The road passes through the old mining town of Shasta, remarkable for its iron doors and shutters, which suggest the former prosperity of what was once the most important town in northern California. The cost of hauling freight to the La Grange mine from Redding is 1 1/2c. per lb. and the cost of hauling supplies and rails for rifle-bars is the chief item of expense.

The deposit which is being worked is an old channel running across the divide between Weaver creek and Oregon guleh. It can be traced by the outercrop of the schistose rock forming the north side of the channel. The south side of the channel is a soft shale, separated from the harder rock by a band of clay, which gives considerable trouble in the operation of the mine. Since the deposition of the gravel the strata have been slightly tilted, as shown in the section of the mine (Fig. 1). Near the bedrock the best gravel occurs, together with large boulders. Above this is a band of hardpan, which sometimes requires blasting. This, however, is expensive, and an important economy in operating costs has been effected by keeping the face of the gravel perpendicular, so that the weight is sufficient to disintegrate the cemented material, and thus the pressure from above is used in a way similar to that employed in breaking coal. Above this the gravel is of finer texture but of poorer grade. The entire mass constitutes a bank about 450 ft. high, yielding from 1 to 25c. per cu. yd., the average value of the material washed being about 3c. per cu. yd. The gravel deposit is of enormous dimensions, and the operation of the mine will probably be continued for several decades.

The development of an adequate water supply has been the most expensive part of the enterprise. The system includes 21 miles of ditches, 15 miles of flume, with several tunnels, one of which is 2 miles long, and three inverted siphons of 450, 600, and 1100 ft. depression, respectively. Stewart’s fork of Trinity river is the principal source of water supply, and this is now being increased in quantity by utilizing the lakes at the head of the river as reservoirs. The main ditch is 27 miles long, of which 8 3/4 miles are flume. This is 7 ft. wide at the top, 2 ft. wide at the bottom, with 5-ft. posts. A tunnel 2 miles long penetrates the divide between Stewart’s fork and Rush creek. The three inverted siphons, one of which has a depression of 1100 ft., are of pipe from 26 to 30 in. diam. The ditch leads into a reservoir at an elevation of 650 ft. above the mine-workings, and has a capacity of 3000 miner’s inches. As this is not sufficient to operate continuously, the water is accumulated in the reservoir above the mine.
The giants are kept at work about 21 hr. per day when there is a good water supply, and during the intervals large boulders are removed and general repairs are made. The economic handling of these boulders is of the utmost importance. Derricks are used in preference to traveling cable-crane, and as many boulders are removed as possible by this means, and these are piled up on the side of the channel. The derricks are operated by water-power. The larger boulders, especially those out of reach of the derricks, are drilled by hammer machines and blasted.

The giants are worked by hand, but electricity has been tried as a means of control, as it is desirable to place the giant nearer to the bank than is consistent with safety to human life. Magnets were used as a means of control, but the danger of short-circuiting and subsequent turning of the giant was found to be too serious. It is proposed to test a machine directed by compressed air, with electrically controlled valves, as a means of working near the bank without danger to the operator. A recent improvement has been made in the giants used by means of which the risk of accident is reduced. Lugs are cast on the giant, to act as a safety-catch if the king-bolt snaps, and the top of the giant breaks off.

At the Le Grange mine the gravel is entirely washed down by under-cutting with water, and no large blasts are necessary. The débris is then washed down the sluice-box, which consists of an armored canal, through which a constant stream of enormous boulders and sand is continuously rushing. A few men are kept to tend the boxes and to loosen with steel bars the accumulations of rocks which form in the boxes from time to time. This work is somewhat dangerous, as large boulders are liable to strike the bar and throw the man into the sluice-box, if he happens to be on the wrong side of the bar. If these accumulations are not quickly removed, the entire sluice-box is liable to become filled in a few minutes and overflow. Operations must then be stopped until the box can be emptied sufficiently. The laborers thus employed work 12 hr., and are paid 30c. per hr., the work being wet and disagreeable. In the interval during which the water is shut off these men work at the derrick removing boulders.

The sluice-boxes are 4 by 6 ft., in cross-section, and are let into the bedrock at the bottom of the channell with a uniform grade of 8 in. per 12 ft. As the work advances new 'boxes' are let in, that is, a 12-ft. length is added to the sluice, and the cut in the bedrock is advanced after being thoroughly cleaned up by the giants. On the north side of the mine, the bedrock is hard and easily cleaned, but the south side is a soft shale, and this is less easily cleaned. At the contact a thick blue clay occurs which is very stiff and plastic, and the masses sliding on the bedrock are a serious inconvenience. Of the gold recovered 90% is found in the first 400 ft. of sluice, and the remainder in the next 200 ft. The sluice is armored with steel rails, as the continuous stream of boulders, sometimes 3 or 4 ft. diam., wears out the steel riddles in a few months. The rails are laid close together, at first longitudinally with transverse lugs, being supported on 2 by 6-in. wooden strips, forming a riddle 10 in. deep. The sluice is continuous, but each length of 12 ft. is called a 'box,' a term derived from the smaller sluice-box of plank. Each box is built of 3-in. lumber, the bottom being lined with rails, and the sides with one rail laid longitudinally, held in place by blocks of wood fitting closely above these. The first 8 boxes, that is, 96 ft., are lined with rails laid longitudinally, held in place by 2 by 4-in. slotted bars. These hold the ends of the rails so that they alternate with one another instead of being directly end to end. Thus any particles of gold that may slide along one rail will fall into the riddle between the next length of rail. The rest of the boxes are lined with transverse steel rails, kept apart by cast-iron lugs, and supported on 2 by 6-in. wooden pieces on edge, kept at proper distance by 4 by 6-in. wooden blocks. These transverse pieces with the blocks attached are kept in stock, and also the rails prepared with lugs. The steel rails used weigh 40 lb. per yd. and are kept apart by 3 and 5 lugs alternately, as shown in Fig. 4. A set of rails wears out in about six months of...
steady work. The rails come from the mills cut to 6-ft. lengths and drilled ready for the cast-iron lugs to be bolted on. The latter are made in San Francisco, and weigh five pounds each. One 6-ft. length of rail, with lugs attached, costs $5 delivered.

Great difficulty has been experienced in keeping the rails from becoming dislodged by large boulders. This has now been overcome by the method of lining the sides. At first a block is laid in, shaped to fit close to the web of a rail, and above this a rail is laid longitudinally. This is held down by another block similarly shaped to fit the rail, and above this another block and a longitudinal strip of 3 by 4-in. timber completes the lining. Each of the 130 boxes are 12 ft. long and contain 30 transverse rails. At a point

960 ft. from the head of the sluice-boxes, the débris is thoroughly turned, and the water is churned up by a fall of 8 ft. This ensures the arrest of any gold that may have escaped the upper riffles by flotation. The bottom of the sluice-box at the fall is protected by an accumulation of rocks, and this is provided with a derrick to remove large boulders, and with a by-pass to allow the water to pass in ease of a blockade. At 1380 ft. from the head of the sluice a fork is made by which the gravel can be diverted by a steel door to either one of two sluices. In this way the area of dam available is increased, and an alternative is ready when the sluice-boxes become blocked. As work progresses the length of sluice continually increases at both ends, owing to the enormous quantity of material dumped. When the mine is running at full blast, with four giants, the amount of material treated is 1000 cu. yd. per hr.

The débris produced each season amounts to several

million tons, but this is discarded into the Trinity river, or is deposited on valleys and farms owned by the company. Litigation is thus avoided.

The cost of hydraulic mining by yardage is not easy to determine, owing to the difficulty of estimating the amount of material removed. The only factors that can be accurately measured are the quantity of water and the cost and value of the gold produced, as an accurate survey of a large working-face is expensive and dangerous. It is customary, therefore, to calculate the cost and production per miner's inch of water for purposes of reference. The probable cost per cubic yard can be found empirically from results showing the yardage removed by a known quantity of water during a long period. The
IRON, STEEL, AND FUEL IN CHINA.

Written for the MINING AND SCIENTIFIC PRESS
By W. D. B. DODSON.

China has in operation, on modern lines, her first iron mine and reduction plant. Production is not large as yet, but the cost-records established assure rapid expansion of the industry. China will become an important factor in the metal markets of the Pacific countries. Sheng Kung Pao, the wealthiest and most active of China's workers for progress, has just perfected a re-organization of three companies, bringing together the Hanyang Iron & Steel Works, the Tayeh iron concern, and the Pinghsiang collieries, the capital of the new company to be 20,000,000 tael (about $11,600,000). Of this capital 10,000,000 tael has been used in purchasing the properties, and 10,000,000 tael will be employed in extensions and improvements. The property acquired consists of a steel-plant and rolling-mill of 1000 tons daily capacity, furnace-plant of 800 tons capacity, an iron mine now producing more than 1000 tons of ore daily, and a colliery yielding 1000 tons of coal daily, of which latter about 800 tons are eoked at the mine. The plant of the company also includes 60 miles of broad-gauge railway, with complete equipment of rolling stock for freight and passenger traffic, 15 miles of narrow-gauge railway and equipment, one 1000-ton steam lighter for river trade, and a big fleet of launchers, tugs, barges, and so forth.

I recently visited these properties. It is apparent that the present tonnage will soon be greatly increased. Another furnace of 250 to 300 tons capacity is being added to the reduction plant at Hanyang. One has just been completed, and more will follow. The rolling-mill is now unable to deliver steel rails to supply the demand for the Chinese railways, which are required to give preference to the home company. At the Tayeh iron mine the ore for the Hanyang furnaces is produced, and 150,000 tons per year is shipped to Japan for the Japanese Imperial steel-plant at Wakamatsu. Drill prospecting will be commenced soon to determine plans for installing a big plant for more economical and extensive mining operations. The yield at Tayeh is to be brought up to many thousands tons daily as quickly as the management can attain this end. At the Pinghsiang colliery a coking plant of 4000 tons capacity has been erected, and galleries run in the mine in preparation for a greater production.

A great area of iron-bearing land is owned by the new company. Mining is in progress at Tayeh only. Three big cuts have been made on one vein, and ore occurs between massive limestone on the foot and a diorite hanging wall. At all three cuts, the two most widely separated being nine li (three miles) apart, there is a uniform width of about 60 yd. of ore. Next to the diorite wall an excess of silice is found, but otherwise the full width is mined. Practically all ore taken out is a red hematite of high metallic content, the contract with the Japanese requiring for first grade 62% of iron. A magnetite deposit of rather limited area has been mined on this same ore- seam, adjacent to one of the present hematite cuttings, and ore cropings only have been mined so far, each of the three cuttings being on sharply sloping buttes, the work starting a few feet above the valley level, that is barely higher than the Yang Tse river. A supply for several years of extensive operations is in sight, without pumping, hoisting, or further exploration. One foreign geologist who reported on the property for the Chinese Government estimated a possible output of 1,000,000 tons per year for 100 years. His estimate was based upon the surface showing in cropings for a distance of nearly three miles.

All mining at Tayeh is by hand. Chinese coolies perform all the work, under the supervision of a foreign superintendent. They are paid on an average 250 cash per day, the equivalent of which is about 25c. Mex. or 10c. gold, as exchange rules. One coolie accounts for about one ton of ore daily, making the mining costs about 10c. gold per ton. From the slope-dumps the ore is delivered upon the ore cars, that haul it 15 miles to the Yang Tse river, where it is discharged upon the bank, and then carried by coolies aboard ocean steamships or lighters. The 15-mile railway haul and loading-costs bring the total working-charge against the ore to the time of delivery on board up to about 50c. silver, or 20c. gold. Steam-shovels will soon be installed and modern handling devices adopted.

Tayeh is 80 miles below Hankow, on the Yang Tse river, and 600 miles from the sea. Ocean-going steamships can reach Hankow and Tayeh during five or six months of the year, and the river has 10 to 15 ft. of water at the lowest season. Steamships of 1000 to 4000 tons run alongside the shore, and the ore for Hanyang is loaded into 500-ton barges, which are toed to their destination, 80 miles distant, Hanyang being in the city of Hankow. It is said that the cost of ore charged into the furnace at Hanyang runs as low as 80c. per ton. The Japanese contract for ore was for 30 years, and has been in force less than four years.

Both manganese and lime for the furnaces are secured within a few rods of the ore deposit, and shipped with the ore. Prospecting and development on other iron deposits are to be taken up rapidly. Japan holds forth promise of taking all surplus pig or ore for many years, and will doubtless be the most important consumer outside of the home market.

While the new steel plant was being erected the old furnaces of 500 tons capacity delivered pig for foreign markets. One shipment of 10,000 tons was made to the Atlantic coast of America, and found ready sale. Greater quantities were sent to the American Pacific coast.

The Hanyang steel plant was installed by a Chinese metallurgist of foreign training, V. K. Lee, now general manager of the new company. He traveled through America and Europe, accompanied by experts, testing his own ores and advising with leading metallurgists. The Siemens-Martin process of reduction was decided upon. The steel plant was of the latest type at date of order, in 1904. The molten metal is to be conducted direct from the furnaces to the steel ereibles, and furnace gases used by an
elect tric power plant, which will supply the Hanyang steel plant with light and some power for the city of Hankow. A 100-ton steam lighter, specially built for handling rails and structural material, has been put on the Yang Tse by the company to convey the company's products to Shanghai and other river ports. If it is successful, and others are needed, a fleet of five more is to follow. These will enable the company to deliver direct to the largest ocean steamships, when seeking foreign trade.

A modern mining and coking plant has been erected on the Pingshiang coal mine. Its output can be brought up to 3000 to 4000 tons per day, as the market opens. Extensive development has been carried on, exposing exceptionally strong seams of high-grade coking coal. A beehive oven plant of 4000 tons capacity has been completed. This coke product has proved satisfactory for metallurgical purposes. Japan has been buying considerable quantities, and will be a heavy consumer, as the Pingshiang product has been able to compete with the best of Japanese products. The coke is now offered to the world, delivered at Shanghai. The 60 miles of broad-gauge railway between the colliery and Siang river—a tributary of the Yang Tse—is good work, and all equipment is modern. From the river-port terminus of the railway to Hankow is a distance of 240 miles, and steam launches towing big barges convey the coke and coal to that city, where it is used by the company or sold to any bidder.

Hanyang's probable output in the near future is difficult to estimate. It will doubtless increase rapidly.

Another modern furnace-plant has been erected in China by the Chinese. It was in Yunnan, and proved a dismal failure, because of ignorance. The enterprise at Hanyang is financed by Chinese capital, but care is taken by a sagacious management to retain experienced foreign help and supervision.

Hunan province, with its great anthracite district and its other minerals, and Shansi, with its vast bituminous coals and iron deposits, are the next districts to command attention. The Peking Syndicate secured a concession to mine in the latter, with a proviso that a smelter should be erected and the people taught. After much wrangling, Shansi province bought the concession back for 3,500,000 taels, and now the great iron district has no other type of reduction plant than the primitive creel over a coal fire. Hanyang's success under modern methods is expected to stimulate all parts of the empire.

**PRODUCTION OF LEAD IN 1907.**

The total domestic production of refined lead in 1907, as given by C. E. Siebenthal of the U. S. Geological Survey, was 414,189 short tons, of which 314,241 tons was de-silverized lead and 99,948 tons was soft lead. In 1906 the production of de-silverized lead was 313,886 short tons; of soft lead, 90,783 tons; and the total refined lead was 404,669 short tons. The increase in production of 1907 over 1906 was therefore 9520 short tons. The total for 1907 includes all de-silverized lead produced in this country, and the pig lead recovered from the Mississippi Valley lead ores, but is exclusive of 9910 tons of antimonal lead reported by refiners. Of the pig lead from the Mississippi Valley ores, 29,809 tons was de-silverized, and was therefore not included under 'soft lead.' The product of refined lead cannot be apportioned according to the sources of ore from which it was derived, because the lead refiners treat also products that are secondary and those that are derived from diverse sources. The identity of ore, and thus its original source, is preserved only as far as the smelters. The following table, showing sources of lead produced in the United States, is therefore based on smelter figures. It includes 'pig lead' reported by all known smelters running on Mississippi Valley lead ores and 'lead' produced at all other known smelters in this country. No lead ores from the United States were treated elsewhere in 1907. The table gives the sources of lead produced in the United States, in short tons.

1Exclusive of 12,339 tons lead derived from Mexican bullion.
2Exclusive of 9426 tons of lead from Mexican and other foreign bullion.
3Including, according to special reports, 25 tons of lead from Texas.

**Weight of rail** required per mile of track is equal to the weight of one rail, in pounds per yard, divided by 7 and multiplied by 11. The result is the weight in tons of 2240 pounds.
DECLINE AND REVIVAL OF COMSTOCK MINING.—I.

Written for the Mining and Scientific Press
By Whitman Symmes.

Comstock affairs are in a ferment. The people who pay the assessments are disgusted with the 'trustee' system and its failure to use their money for real mining. Early in 1908, a few shareholders appeared in the offices, had their stock entered in their own names, and commenced to give a little friendly advice. How much this may mean for real mining on the Lode will be appreciated when it is remembered that (with one brief exception), no shareholder has been in evidence on the Comstock horizon since the days when Mackay, Fair, Jones, and their associates fought the difficulties of deep mining, and retired, defeated, to spend their lately gathered hoards amid the ease of more congenial surroundings. It will not be surprising if the Comstock Lode enters upon a new phase, for it has passed through seven distinct periods already. First came the era of the surface bonanzas, then the lean years when all the mines were sinking through porphyry, and then came the boom of the big bonanzas. Next followed the period of deeper exploration and defeat, which was succeeded by an era of low-grade mining, when the mines were entirely in the hands of the thieving millmen. Then followed a series of degenerate years during which the mines ceased to be mines, but were merely names with which to gamble. But after the long decline there came a slight revival of interest. The Comstock Pumping Association was formed, followed by the Ward Shaft Association; the water in the north-end mines was gradually lowered, and, as a consequence, some orebodies were found. And now, in 1908, the faint-hearted revival is at last given a little vigor by signs of the return of the stockholders, to manage for themselves the reopening of the mines and to put to an end, it is to be hoped, the false pretensions and illegitimate methods of the 'trustee' system.

The era of deep mining, from 1878 to 1886, did not begin under entirely favorable circumstances. The year 1877 ushered in hard times upon the Comstock, and so it seemed worth while to sink another thousand feet. The public, which was contributing the assessments, knew that most of the men who had made fortunes from the mines had backed their faith with their money during those discouraging years from 1864 to 1871, when scarcely a mine had any ore in sight. Sharon, manager of the Virginia branch of the Bank of California, together with Ralston, Hayward, and Mills, had formed their Mill & Mining Co. in 1867 to take over the bank's loan to the mills, at a time when the bank directors insisted that their institution must be relieved of its perils burden. Mackay had taken his first-won money, which came as dividends from Kentuck, and had invested it in exploring the immense quartz reef in Bullion, of which he became superintendent. He had found nothing there, but plunging again, he and Fair had obtained control of Hale & Norcross on a big slump in 1869. Within two years that mine had paid $728,000 in dividends, and Fair and Mackay, backed by Flood and O'Brien, had paid out their share of the winnings exploring the 1150-ft. level of the Con. Virginia and the California and in buying up control. John P. Jones, superintendent of the Crown Point, had vainly run drifts and cross-cuts through unpromising por-
phyry for nearly three years before he had opened up the Crown Point-Belcher bonanza on the 1100-ft. level. The public knew these things, so it paid the assessments, and the better known mines were enabled to sink their shafts through the second barren horizon.

There were, and are, three conditions affecting deep mining on the Comstock that make the work different from deep mining anywhere else. In the first place, the rock is hot. At a depth of 2000 ft. it originally had a temperature of from 120 to 130° F. Off in the hanging wall, many hundred feet from the main lode, the Combination, Foreman, and Jacket vertical shafts, at about 2000 ft., had temperatures in the dry rock of 118 to 121° F. In consequence of this heat, little exploratory work could be done until drifts and shafts had been linked together into a ventilating system. The 1750 and 1850-ft. levels of 2000-ft. station that was 157° F. The water in the Yellow Jacket sump at 3080 ft., in 1880-82, stood at 170° F. At the present time the Con. Virginia and the Ward shafts have hot water, about 130°, and the latter has reported as high as 160°. When hot springs are encountered, drains must be dug and covered boxes installed, to keep the water from filling the workings with steam. The 2250-ft. level of the Con. Virginia toward Ophir is planked and eaulked for several hundred feet in order to keep the hot water and steam. This form of construction, which is locally known as 'snow-sheds,' is now also being installed on the 2350-ft. level.

The third unusual condition in the Comstock is the marked distribution of the water in reservoirs and pockets of water, which have often drowned the pumps for weeks and months at a time. Many mines have water-pockets, but I know of no other district where such an uneven distribution is to be expected. So fearful did the miners become of the water-pockets during the period of deep mining, and so quickly did they turn the drifts aside from ground that was wet, that one wonders whether they were not really prospecting for a dry place in which to work, instead of for ore. The diamond-drill was first introduced for the purpose of exploring for orebodies, but the public would place no reliance in the results. In the words of the Virginia Enterprise, the diamond-drill was "considered by many to be a swindling tool, invented by either Jim Fair or the devil." But it was found to be of immense service in giving notice
of approach to the water-pockets, and it came into universal use.

When the mines got down to their 2000-ft. levels most of them were working through the second line of shafts; some of these were inclines, others cut the lode vertically at ten or twelve hundred feet, and were continued thence as inclines. With scarcely an exception, the lower levels were first opened through winzes. At the same time, a third line of shafts was sunk farther east, to cut the lode at greater depth, and to give ventilation and pumping facilities to the suffocating and half-drowned winze system. In no case did an east shaft fulfill the function for which it was designed. Those that reached the lode had no sooner done so than they found more water than their pumps could handle, or than their disgusted and over-grafted stockholders would pay to have removed.

The new Yellow Jacket shaft, to cut the lode vertically at about 2700 ft., was started early in 1877; to meet it drifts were run from the 2300, 2500, and 2700-ft. levels of the old workings, and made an air-connection on the 2500-ft. level in 1879. To the south of the Yellow Jacket, the Crown Point and Belcher put down their joint pump incline to the 3000-ft. level, but, apparently, they forgot something, for they left their main pumps behind them on the 2560. The Belcher found what looked like the top of an orebody on the 2760, and started to get under it on the 3000-ft. level. On the latter level in 1880, the miners encountered all the water the pumps could handle and the work was practically brought to a stand-still.

On the north, the Yellow Jacket workings connected with those of Confidence, Challenge, Imperial, Alpha, and Exchequer. In 1877, while exploring their 2400-ft. level, the Exchequer men encountered 10 miner's inches of water. The drift was immediately bulkedhead, and the exploration was turned to the west. Possibly they thought that they never would have to contend with that particular body of water again. Some low-grade quartz stringers were cut on the 2400, and in 1880, Exchequer drifted north from the new Yellow Jacket shaft to get under those quartz stringers on their 2810 level. Some more quartz stringers were cut, and then the diamond-drill tapped a flow of 20 miner's inches of water. About the same time a drill-hole from the Yellow Jacket shaft, at a depth of 3080 ft. tapped a heavy flow of water, and the total influx overcame the pumps. By January, 1881, the water had risen above the 2900-ft. level and cut off the last air-connection between the new shaft and the old workings. Crown Point and Belcher, on the south, were flooded too. Alta, a mile away on the southeast fork of the lode, and not directly connected with the Yellow Jacket by any workings, was flooded a couple of weeks later, but probably from an independent source.

The Gold Hill pumps were kept running steadily. Early in 1881 the south lateral of the Sutro Tunnel reached the 'Jacket' shaft, thereby saving the pumps 1514 ft. of lift. By January, 1882, the miners were once more working on the deepest levels, and the Exchequer men were cleaning out their 2810-ft. drift, which had been caved by the flood. The Jacket pumps were then lifting 700 gal. per min. On February 12, 1882, the Exchequer men were back to where their drift had tapped about 225 gal. per min. more than a year and a half before. With the suddenness of an explosion, the miners were struck by a great rush of hot water, and barely escaped with their lives. When the boosts were removed from one of them, the scalded skin was torn off too. The water from the drift was estimated at 1350 gal. per minute. The Yellow Jacket shaft was at that time the deepest on the continent, and its pumps were the heaviest that had ever been built. They were compound, steam-driven, Cornish pumps lifting 160 gal. per stroke. By speeding up to 7.2 strokes per minute (which was considered the limit of safety), and by running the bailing-tanks, about 1500 gal. per min. was removed. The water rose rapidly. When it had reached the 2700-ft. level, the influx at the Jacket shaft was estimated at 1900 gal. per minute; when at the 2500-ft. level, 1530 gal.; and at the 2300-ft. level, 400 ft. above the Exchequer drill-hole, it still amounted to 1180 gal. The water flowed south from the Jacket into the 2500 and 2700-ft. workings of the Crown Point, through the 2560 and 2760 of the Belcher, and into the 2275 of the Overman. To the north, the Confidence, Challenge, Imperial, and Exchequer were under water too. At the end of February, the Crown Point-Belcher pumps were stopped. Then came the wrangle between the different companies as to which should pay to pump the water, and what their quota should be. The previous Gold Hill flood had required 18 months of pumping and repairing, but an optimistic estimate was made that the work could be done in six months, at a cost of half a million dollars. Company salaries, office expenses, and general graft were probably not included in the estimate. However, the other companies did not come to the assistance of the Yellow Jacket, and on March 16 the Jacket pumps were shut down, thereby saving that company $15,000 per month. The Bullion mine was not connected with the Gold Hill mines except on its 2150-ft. level; the management paid the Jacket to run its pumps again for a few days, and meanwhile put in a brick bulkhead, thus protecting the Virginia from the flooded workings of Gold Hill. The wrangling over the pumping then went on; Mackay got mad and sold his Yellow Jacket stock, and Gold Hill has been flooded ever since. The Foreman shaft of the Overman, which was then being sunk and had reached a depth of 2390 ft., was necessarily abandoned. There were other reasons than those apparent to the stockholders for the abandonment of the deep-level work. Gold Hill had already entered upon the low-grade era. Its mine managers had discovered that they could transfer larger amounts of the stockholders' money to their own private bank accounts by working the mill game, than by pursuing the work of deep exploration.

Alta conquered its flood of 1882, but in the latter part of 1884 the drifts became very wet. The Gold Hill flood, saturating the lode, had at last reached this mine also. It was found that the Alta pumps
were draining the whole surrounding country. First, they drained the Justice, and lowered the water in Silver Hill 250 ft.; in November, 1884, the water in the Belcher, Crown Point, and Yellow Jacket had been lowered by 300 ft. With both pumps and bail-ingtanks running at full speed, 660 gal. per min. were removed, while the influx was about 800 gal. By December the Alta had lost her lower pumps, and the attempt to keep the mine free of water was abandoned.

It was 1879 when most of the north-end mines got to working below their 2000-ft. levels. In that year the Ophir stope or ore from the Hardy vein down to the 2150 level, paying some dividends, and the Union did a little stoping on the 2300 and 2400 levels. The C. & C. shaft reached its 2500 station in January, 1881, but was never sunk deeper. In the spring of 1882, when Gold Hill was finally flooded, the north-end mines were exploring on their 2500, 2700, and 2900-ft. levels. They kept their drifts to the west of the vein formation for fear of water and relied upon drill-holes and a few cross-ents to explore the forma-

![Combination, Osbiston, and C. & C. Shafts.](image)

tion to the east. The Con. Virginia & California did very little work below the 2000 level. The Union and Sierra Nevada mines did the most, making extensive use of the diamond-drill. Some of the lateral drifts in the north end are said to have been left without a single cross-cut. The Union found some ore on the 2300, 2400, and 2500-ft. levels, the battery-assays running from $30 to $70. The Sierra Nevada also got part of these orebodies, which were at the northern fork of the lode, and not in a promising formation. In 1882 the Mexican stoned some ore on the 2700-ft. level, probably on the same branch fissure as the present Ophir orebody, but at that time it was not considered rich enough to pay. One branch of the Mexican 2500 drift followed this fissure, being 200 ft. below the present Ophir workings, but the mine-mamp shows but one cross-ent there. Access was obtained to the deeper workings through the Union shaft to the 2700 level and through the Ophir incline, which stopped at the 2500-ft. station. Winzes were sunk to the 2700 level and others to the 2900, and in 1883, the Mexican-Ophir winze, on Mexican ground, was sunk to 3100 ft. In June, 1884, the Mexican, Ophir, Union, and Sierra Nevada united in sinking this winze to the 3300 level, all other work being stopped to save expense. In December, 1884, a di-

mond-drill hole from the bottom of this winze tapped a large flow of water. The pumps in the winze were utterly inadequate. The flood rose 400 ft. in 90 hours, and the deep levels of the north end were abandoned. By October 1, 1885, the water was up to the 2000-ft. level.

The Comstock Lode was thus flooded at its two extremities, but the middle (Virginia) mines still had access to their deeper workings. The principal shaft in this territory was the Combination, belonging to the Chollar-Potosi, Hale & Norcross, and Savage companies. It eventually reached a depth of 3250 ft. North of it was the Osbiston, belonging to Best & Belcher and Gould & Curry, which was put down 2450 ft.; and south of it was the Ward shaft, belonging to the Bullion and Julua, which reached the same depth. The middle mines first opened their low levels by means of the Fair shaft (and incline) of the Hale & Norcross to the 2400-ft. level, and the Savage incline to 2200 ft. Below that they worked through winzes. Water was abundant, the ground was infernally hot, and ventilation was insufficient for active work. The Combination shaft got a connec-

tion to the old workings through the Lightning drift (2000 level) from the Hale & Norcross, in January, 1879. The Savage and Norcross were then flooded in their lower levels. In January, 1882, the Combination started a pump run by hydraulic transmission, at first using steam-power, but later using water-power from the Virginia & Gold Hill Water Co.'s ditch. It was placed on the 2400 station, and discharged into the Sutro Tunnel above. This was to assist the steam-driven Cornish pumps. In 1884 it was found necessary to install another hydraulic pump on the 2600, and sinking was then resumed. A third hy-

draulic pump was placed on the 3000 level in 1885. As fast as pumps were installed they were found to be working at full capacity. Bullheads were installed to shut off the wet drifts, drill-holes were plugged. Drifts were kept to the west, for fear of water. There were long delays waiting for new pumps, during which time it was not considered safe to cross-cut from the lateral drifts for fear of getting drowned. Several times the lower stations were flooded for brief intervals. Ventilation was insufficient. The heat was intense. In one drift the miners were pushed to the face lying on a car and sur-

rounded by ice.

In January, 1885, the Hale & Norcross cut 3 ft. of quartz on the 2500-ft. level, and cut the vein again later on the 2900, where it was 8 ft. wide. It was claimed that it would mill $25 to $35. On the 3000 level the orebody was wider and better. Some ore was stope out above the 3100-ft. level and yielded
about $5000 in bullion. The orebody appears to have been low-grade, but stringers contained some of the finest 'specimen ore' ever seen on the lode. The formation led north, and Gould & Curry and Best & Belecher thought it worth while to pump out the Osbiston shaft, planning to sink it to 3000 ft. Its lower portion had been abandoned in 1882, and the water stood below the 1850 level. By September, 1886, it had been pumped out and a bulkhead had been finished on the 2319 level to shut out a heavy flow of water from the north. In the latter part of that month the north lateral drift of Hale & Norcross tapped a few inches of water. The Combination pumps were then running at their maximum. Early in the year they had been handling well above 4,000,000 gal. per day, and they were rated at about 5,000,000 gal., or nearly 3500 gal. per min. It became necessary immediately to install another pumping unit. Hale & Norcross and Chollar-Potosi were willing, but the third joint-owner, Savage, refused to contribute. The north-end mines had followed the lead of Gold Hill and gone into milling low-grade ore from the upper levels. Savage had tried it, too, and two months before had commenced to hoist some rich ore from its 600-ft. level. The orebody was being cut on the 800 level and was thought to be large. Real bullion looked good to the Savage directors, and they ceased to take further interest in an exploration of the 3000-ft. level. The stock market was weak and the other two companies could not, by themselves, raise enough money to continue the work. The hydraulic pumps alone were said to be costing $10,000 per month for water-power. In October, 1886, pumping at the Combination shaft was stopped. The 2319-ft. level of the Osbiston shaft was then being cleaned out, preparatory to starting a deep winze in search of a northerly continuation of the Hale & Norcross orebody. As soon as the Combination stopped pumping, the Osbiston was necessarily abandoned too. The fears of Church, Becker, and Lord, in their books published five to ten years earlier, had been fulfilled. The water had conquered. There was no longer any deep mining on the Comstock Lode. But the millmen were getting very busy, as will be shown in the sequel.

The pig-iron production of the United States in 1907 amounted to 25,781,361 long tons, as compared with an output of 25,307,191 tons in 1906 and of 22,992,380 long tons in 1905, according to a report recently published by the U. S. Geological Survey. The smallness of the increase shown by 1907 over 1906 is due to the falling off in demand and production during the last quarter of the year. If the rate of output of the first half of the year had been maintained, the total production of pig iron in 1907 would have been 27,000,000 tons. Of the total amount, Pennsylvania produced 11,346,549 long tons, or 44%, and Ohio 5,250,687, or 20%. Illinois, Alabama, and New York rank next, in the order named.

A memorial window to Sir Benjamin Baker is to be placed in Westminster Abbey by the Institution of Civil Engineers.

---

**CUBAN GOLD MINING.**

Written for the *Mining and Scientific Press* by Edgar W. Denison.

For many years the island of Cuba has been producing copper in considerable quantities. The iron output has also been important. Only recently, however, has the production of gold been sufficient to merit mention. The Holguin-Santiago Mine Co. shipped over $20,000 last month in gold bars. This mine has been taken over by a Cuban company, under the direction of José M. Govin, the editor of the newspaper, *El Mundo*. New installations are contemplated and the chief engineer, W. F. Gray, has recently reported excellent prospects on a number of new claims acquired by the company. The adjoining mine, La Casualidad, has about 30 men employed, under the direction of J. F. C. Abelspies, an English mining engineer. The enterprise has been taken over by Albert Wright, a prominent lawyer of Havana, who is to re-organize the company and raise additional capital for development. A few days ago, at the 85-ft. level, a 14-ft. vein was cross-cut, and the assay showed an average higher than any yet found in that district. Another undeveloped mine, on the same vein as the Holguin-Santiago and La Casualidad, to the east, is called Relámpago, while to the east of that is La Caridad, owned in Havana.

The outlook for the early development of gold on an important scale in Cuba is promising. It has always been contended by the natives in the Province of Santiago, in which these mines are situated, that gold was produced in paying quantities many years ago in this same region, the Indians washing it out and using it in trading for provisions.

J. D., Black Bear, Cal.: No. 1, metamorphic shale with pyrite; No. 2, hornblende andesite.

J. K. R., Walkerville, Mont.: No. 1, tourmaline in quartz and a decomposed mineral probably feldspar.

W. B. H., Shasta county, Cal.: No. 4, rock impregnated with cuprite and malachite, and some unaltered chalcopyrite.

C. W. M., Goldfield, Nev.: No. 1, metamorphic rock consisting of feldspar, quartz, and calcite in which are limonite after pyrite, and a black mineral occurring in very thin foliae and dentritic forms in small cracks. The actual amount is so small that from the specimen not enough could be obtained for tests; No. 2, decomposed hornblende andesite.
AN INITIAL COAL-SUBSTANCE WITH A CONSTANT THERMAL VALUE.

By S. W. Parr and W. F. Wheeler.

*From a number of sources there has been developed the idea that in any given type of coal, or perhaps less broadly, in any given deposit of coal, there exists an initial substance with certain uniformities as to composition and calorific value, which might make it serve as a basis for very important considerations, both of a technical and a scientific nature. To be of special advantage, such a unit-substance should be constant within rather narrow limits. Great value will attach to the fact if it may be proved that in any given case there is a unit-coal with fairly definite heat-value. For a given region or mine, for example, where such values were established, it would be possible to calculate heat-units upon the simple determination of the extraneous material such as water, ash, and sulphur. Or it would be possible to correct heat-determinations or confine them within the limits of variation recognized as inherent in the unit-substance. Especially, also, would such a unit-substance serve as a basis for studying losses by oxidation or other processes of deterioration.

Probably the first recognition of such a unit is found in a discussion by Lord and Haas.† From numerous analyses of Pennsylvania and Ohio coals, they draw a comparison between the heat-values as derived by Dulong’s formula, the Manley calorimeter, and those calculated from a unit-value which they designate as ‘H’ and describe as being the value for the ash, water, and sulphur-free substances. They find the sulphur to be a disturbing element, and correct for it in a partial manner only. However, they are justified in the conclusion that ‘on comparing the results, seam by seam, it would appear that the actual coal of a given seam, at least over considerable areas, may be regarded as essentially of uniform heating value.’ The expression ‘actual coal,’ presumably refers to this same initial or unit-substance, free from extraneous matter, such as ash, moisture, and sulphur. The idea is evidently intended in the further quotation below, though the same qualification as to ‘actual coal’ is not used.

‘The results of our tests seem to indicate that the character of a coal seam, as far as its fuel-value is concerned, is a nearly constant quality over considerable areas. The determination of the value for seams would be of great use, as the rapid proximate analysis, or, for that matter, merely the determination of ash and moisture in low-sulphur coals, would be sufficient to grade coals of the same vein. Of course, it is dangerous to argue from so few examples, but the proposition seems reasonable.’ ‡ Kent, in discussing this paper in the same volume (p. 946), says: ‘The conclusions of the authors that the ‘actual coal’ (moisture and ash excluded), of a given seam over considerable areas, may be regarded as of uniform heating-value, is one of great practical import. I have held the same position tentatively for a long time.’

Another development of this general idea is found in numerous articles by A. Bement of Chicago. For example,† referring to the advantage of having certain units of reference, he says: ‘The possibility of the more extended use of constants is presented, and the author urges the feasibility of considering the pure coal compositions as constants for a coal seam, or particular locality of such seams. This possibility has been suggested, principally by the fact that the heating power of the pure coal from a general locality does not vary over greater limits than that of the calorimetric method, and he has been able to employ it as a constant in calculating the heating-power of dry and moist coal, having determined only moisture and ash, and obtained results that check with calorimetric determinations made on the same samples.

The author, however, does not claim originality in this observation, but does insist that the use of such constants is of advantage. . . . This view concedes that coal from a certain locality or seam does not vary in quality, but that the variation is due to the presence of ash and moisture, which are imperfections associated with coal.’

It is evident that several variables fail of recognition to the extent that they are not included in the extraneous matter of the vein-substance, and since they certainly do not belong to the ‘actual coal,’ the question arises as to whether or not we yet have a fair basis of reference for drawing conclusions as to the constancy of our initial coal. For example, in coals of the western or bituminous type, the sulphur may vary from 1 to 5, or even 6%. Variations of 2 or 3% may be possible within the product from the same seam, especially where washing of the coal is in vogue. Now, if this variable is thrown into the ‘actual coal’ content, it, by so much, prohibits any constancy of heat-values being credited to that hypothetical constituent. The same thing is true of water of hydration. If the shale-constant of the ash has, for example, 8% of such water of hydration, and the same is not counted with the ash, but as part of the ‘actual coal,’ here again is a disturbing element quite as troublesome as the sulphur. Similar variables would accompany the presence of gypsum or calcium carbonate. The result of extensive investigations has led to the conclusion that such a ‘unit-substance’ does exist, and consists of the ordinary coal free from moisture, clayey-ash, hydration of the clayey-ash, iron with the necessary sulphur to constitute pyrite, and the remaining sulphur undetermined as to its combinations.

An aluminum carbonate has recently been prepared by M. Gawalowski. At a pressure of eight atmospheres a perfectly soluble polycarbonate is formed. As this pressure exists at a moderate depth in the earth’s crust, and the decomposing action of carbide acid on silicates is known, which are thus transformed into carbonates, the formation of bauxite deposits by thermal springs containing aluminum carbonate in solution can be explained.
MINING AND METALLURGICAL PATENTS.

Specially reported for the MINING AND SCIENTIFIC PRESS.

ROCKY STAMP MILL.—No. 897,214. Philip J. Loner

gan, Denver, Colorado.

A stamp-mill, comprising two concentric circular series of vertical stamps and a superposed and concentric turn-
table extending over all the stamps and bearing on its under-
side a cam-carrying with a plurality of double-faced cams,
arranged between the two series of stamps and acting upon
the same to lift the stamps of both series, and means for
rotating the turntable.

APPARATUS FOR SHARPENING ROCK DRILLS OR DRILL-
BITS.—No. 897,835. Walter E. Kimber, Johannesburg,
Transvaal.

No. 897,835.

In apparatus for sharpening rock-drills or bits, a tool for
bringing up the corners comprising a striker having a con-
cave striking face provided with a fluted cutting edge, said
face having a groove to receive the upper vertical wing of a
drill or bit when the striker is operating on the horizontal
wings of said drill or bit to impart the bevel to roughly
form the cutting edge, and means for operating said striker,
in combination with an anvil formed to hold the drill or bit
to present said horizontal wings of the drill or bit to the
fluted cutting edge of the tool aforesaid.

VACUUM MINING DEVICE.—No. 898,827. Jerry B. Rid-
die, Sacramento, California.

In an apparatus of the character described, a vacuum
chamber, a material receiving chamber connected there-
with, an upwardly closing valve located between the cham-
ers, and mechanical means whereby said valve is posi-
tively opened.

SEPARATING-TABLE.—No. 898,920. Henry M. Sutton,
Walter L. Steele, and Edwin G. Steele, Dallas, Texas.

A concentrating table having a floor free from obstruc-
tions and impervious to the passage of material there-
through, while pervious to air under pressure, in combina-
tion with means for passing air through said floor, means
for causing the heavier and lighter materials to travel in
divergent paths, and separated air-controlling strips secured
in contact with the under surface of said floor and disposed
to form intermediate continuous air passages extending
substantially transversely to the path of travel of the rela-
tively lighter components of the material thereon.

RECUPERATIVE SPELTER-FURNACE.—No. 898,409.
Nicholas L. Heinz, La Salle, Illinois.

No. 898,409.

The retort chamber having a longitudinal division wall, a
gas inlet opening and an outlet opening at opposite ends,
wear the chamber bottom and at each side of the division
wall, a large horizontal flue in the division wall near the
chamber bottom and provided with ports at intervals along
its length and communicating with the space at the bottom
of said chamber on both sides, and a gas supply flue having
common connection with the gas inlet openings and large
horizontal flue.

ROCK-DRILL.—No. 897,336. Robert H. Anderson, Ger-
miston, Transvaal.

A detachable cutting head for rock-drills, comprising a
body portion having a flat base for engagement with a
shank, cutting edges disposed upon the face of said body
portion, and a stem centrally disposed on said base and
forming therewith a rivet-like shaped structure and inter-
ially inclined faces in said head forming a hole centrally
disposed therein, said inclined faces being provided with
grooves, substantially as described.

APPARATUS FOR EXPLODING MINE CHARGES.—No.

No. 898,847.

In an apparatus for exploding mine charges, a main cir-
cuit including a source of electric energy, a normally open
switch included in said circuit, a clock having means for
automatically operating said switch to close the primary
circuit at a predetermined time, a normally open auxiliary
circuit, forming part of the main circuit and including said
source of electrical energy and the mine charge, said auxil-
ary circuit being incapable of being closed to fire the
charge prior to the closing of the main circuit and means
carried by the clock for automatically closing said auxiliary
circuit at a time subsequent to the closing of the switch in
the main circuit.
Richards Pulsator Jig.

The Richards pulsator jig is similar in almost every respect to the ordinary Harz jig, except that by the use of a peculiar form of pulsating current, one square inch of screen surface can be made to do the work of 200 square inches of screen surface of the ordinary jig. This has been substantiated in one of the largest copper concentrating mills in Montana. After this company had experimented with this one machine, which was of 90 tons capacity, another jig of 400 tons capacity was ordered, and both machines are now in operation.

The principal difference between the Richards jig and the ordinary jig is in the absence of plungers and in the fact that there is practically no hutch product made. The advent of the reciprocating concentrating table has demonstrated the manifest advisability of treating the smaller sized ore-particles on such tables, after proper classification, in preference to treating them in jigs. In general, jigs may be used to advantage on ore pulps composed of particles coarser than 1 mm., while particles smaller than 1 mm. should be excluded from the jig-feed and treated on reciprocating concentrating tables. It is not claimed that the Richards pulsator jig can do cleaner work than the ordinary jig, but that it will use much less water and that it occupies a marvelously small space compared to its capacity.

The Richards jig is divided into compartments, in the same way as an ordinary Harz jig; it has a screen dividing the hutch compartment from the upper compartment on which the bed of ore is formed; it has side discharge gates and a tailing discharge, and the compartments are arranged adjacent to each other. In place of the plungers, eccentrics, shafting, pulleys, and so forth, which are necessary in the ordinary jigs, the Richards jig has a rotating valve of peculiar design which gives just the right kind of water pulsation to the water.

The total screen surface in the Richards jig is made up of four screens each 4 in. square, or a total of 64 sq. in. for a 90-ton capacity. The Harz jig must have 24 screens, each 17 by 30 in., or a total of 12,000 sq. in., to do equal duty.

The floor space occupied by the 400-ton jig is only 3 by 5 ft., and the screen-surface is only 6 by 14 in. in each of the four compartments. The water used in the Richards jig will amount to 1000 gal. per ton, while in three double-four-compartment Harz jigs necessary to handle the same tonnage it will amount to 4700 gallons.

The action of the Richards jig is extremely simple. The figure shows a four-compartment 90-ton Richards jig in plan, elevation, and section. In H will be recognized the familiar form of hutch with diving-board h. The screen is at S, in the same position as in the Harz jig. Likewise the compartments C, C, C, C, are above the screen S, and have corresponding pockets, P, P, P, P.

The dividing plate between P and Q reaches not quite down to the screen, thereby acting as a seal or gate for the concentrate. Openings D from P into Q are adjustable by vertically sliding gates through which the concentrate discharges into O, thence out to suitable launderers.

The depth of the 'bed' carried on the ordinary Harz jig will probably average from 4 to 5 in. The bed carried on the Richards jig will average 8 to 12 in. This peculiar feature makes the performance of the machine less subject to fluctuation, with the result that the Richards jig, having once been adjusted for a certain class of ore, may remain unchanged while the ore fed to the jig may be lean or rich, or, in fact, the feed may cease altogether, and the jig will still operate perfectly.

In place of the usual plungers and eccentrics there is connected at the top of the hutch a manifold M, by which water supplied through the valve V is distributed to each of the four compartments of the jig. There are four plug cocks connected to the branch flanges of the manifold. The water from the main supply-pipe, which should be under a head of 30 ft. or more, passes through the gate.
valve V to the manifold M under control of the revolving pulsator valve B. The valve B corresponds in function to the plungers in the ordinary jig, yet in its action is radically different in that it gives pulsations of an entirely different character and in one direction only.

The screen S is made up of two layers of brass woven wire cloth, the lower one being 4 mesh and the upper one 20 mesh. In consequence of the fine screen used in this jig a hatch product is seldom made, all the concentrate being discharged in the pockets P, P, P, P, and out through D and O. The material fed to the jig enters through the hopper or trough F over the division plates between the compartments C, C, C, C, and out at the tailing-gate T. In passing through from F to T the particles are subjected to the jiggling action of the upward pulsating current of water through the screen S, with the result that the heavy mineral particles settle in the compartments C to C, and the lighter gangue is carried over and out at the tailing-gate T. The heavy particles settle in C to C, in the ratio of their specific gravity, that is, the heaviest mineral will be found in C, and the lightest mineral in C. The discharge of concentrate or heavy mineral is effected by extending the screen, and consequently the jiggling action, across under the pockets P. All the particles of both mineral and gangue in C are kept in agitation, the mineral being at the bottom and the gangue on top. The mineral at the bottom flows under the division between C and P into P by reason of the pressure due to the height of the column of material in C. Eventually the height of the material in P will become almost as great as C, but for the gate at D, which allows the mineral from P to discharge. By adjusting the height of the gate D the concentrate from P is discharged as fast as it accumulates in the bottom of C, the flow from C to P being maintained by the difference in head in C and P. This simple method of discharging the concentrate explains why it is possible with the Richards jig to feed less rich material to stop the movement altogether, and then start again without readjustment of the machine.

The bed of material, which in C may be as deep as 10 in., will cease discharging concentrate as soon as the level of the material in C drops to the level of the gate D. If gangue only is fed to the jig, it then passes over the bed and out at the tailing-gate. If mineral and gangue are fed to the machine, the mineral accumulates in C, disturbs the balance between C and P until a sufficient amount of mineral is discharged at D to compensate for that which came into C. The gangue that came in with the feed is carried over and out at the tailing-gate.

To feed this small machine, which in the 90-ton size has compartments only 4 in. square, to its full capacity means, as one can readily imagine, that the pulp must rush through like water in a mill-race. It seems incredible that the mineral pulse can be kept inside of the jig for such a short space of time, but, as Dr. Richards said when questioned on this point, "there you will find them." The enormous capacity of the Richards jig as compared to other jigs—1 sq. in. of screen surface in the Richards jig being equal to 200 sq. in. in other jigs—is due entirely to the fact that the water pulsations are all in the same direction upward through the screen. There is no suction or back-impulse of water in the Richards jig. This suction in the other types of jig causes a blinding of the screen at every stroke, which reduces the capacity. Inventors have frequently attempted to get rid of the suction formed by the back-stroke of the jig-plunger by inserting check-valves in the plunger, or by using a plunger driving mechanism giving a quick, slow motion, but with indifferent success. It remained for Dr. Richards to find the correct solution of the problem, and as usual the solution was simple.

The feed to the Richards pulsator jig should be screened to the same ratio of maximum and minimum particles as for successful and efficient recovery upon jigs of the Harz type. The smallest size of material so far treated has been 1 mm. diam. This was done in the 4-in. 4-compartment jig having a capacity of 90 tons per 24 hours. Smaller sizes of jigs have treated still finer material experimentally. The maximum size material as yet treated in the 4-in. jig was 12 mm. (4-10 in.), or coarser than No. 2 mesh.

A Simple 4-compartment Richards jig, occupying 8 sq. ft. of floor space, weighing 1500 lb., requires 80,000 gal. water per 24 hr., and uses 1½ hp, for a capacity of 90 tons, while for similar duty would be needed 3 Harz jigs, each having 4 compartments, occupying 550 sq. ft., weighing 39,000 lb., requiring 425,000 gal. water and 6 horse-power.

A New Wye Level.

We show herewith a new wye level having several improvements, which has just been placed on the market by Wm. Alssworth & Sons, the well known instrument makers of Denver. The principal parts of the instrument are made of the hardest bronze alloys, with the exception of the centres, which are steel. The telescope is 18 in. long, has a magnifying power of 35, is fitted with an erecting or inverting eye-piece, as desired, and has an objective 1¾ in. diam. The level tube is 8 in. long, the bar is 11 in., and is provided with clamp and tangent slow-motion screw. The leveling head is of the four-screw type, of the most rigid construction.

Especially attention has been given to the construction of the telescope, where, owing to improved methods, and by working to within limits of 0.00006 in., it has been possible to construct a telescope that will remain in collimation throughout its entire travel, without making use of the objectionable object-slide adjustment, which until now has been the only solution of this difficulty. The wyes are of light but rigid construction, with improved spring-latches for locking. The clips carry fibre-tipped spring-plungers that hold the telescope firmly in the wyes. The leveling head is of the same construction as that used for transits, but without shifting centre, and owing to especially accurate construction cannot be clamped in any position. The spindle and clamp are protected against the entrance of dust by a light ring threaded onto the spindle, which carries on its inner diameter a felt ring that is in constant contact with a projecting ring on the clamp. The instrument is packed, with the usual accessories, in a mahogany carrying-case, the telescope being removed from the wyes to prevent damage to the collars when carrying and while in transit. This instrument and an improved railroad wye level are fully described in Bulletin BX-9, which will be sent on request.
Air-Blast Transformers.

The accompanying illustration shows an installation of six 500-kw. Wagner Electric Manufacturing Co.'s air-blast transformers at one of the substations of the Calumet & Hecla Mining Co., Calumet, Mich. It comprises part of an installation of a 500-kw., 2300—13,200 volt, 25-cycle, and a 370-kw., 13,200—460 volt, 25-cycle Wagner air-blast transformer, aggregating 16,820 kw., which has been recently put into operation.

The original installation of Wagner transformers consisted of the six transformers shown in the figure, and of three 370-kw., 13,200—460 volt, 25-cycle transformers. In this transmission scheme, power is generated at 13,200 volt 3-phase, and transmitted to various parts of the property. A large portion of the power is transmitted to the substation at Calumet, and is there transformed by the first-mentioned installation of transformers to a transmission potential of 2300 volt for various uses about the mines, such as the operation of pumps, machine tools, and crushers. Another large part of the power, involving the employment of both 370-kw. and 500-kw. transformers, is used in the vicinity of the generating station, for operating motors that of the frequent starting of the large motors employed on the circuits, which causes occasional extremely heavy over-loads. Another feature that had to be guarded against in this installation has been the frequent occurrence of severe electrical storms. The storm period in this region lasts throughout the summer months. The transformers were subjected to frequent lightning discharges, but have, up to the present time successfully withstood them. In one instance the lightning succeeded in getting past the protective devices, and into one of the transformers, but fortunately did no damage beyond burning off a lead, owing to the excellence of the insulation.

The transformer was repaired immediately, and was again in service within a few minutes after the occurrence of the discharge.

The illustration shows six of the 500-kw. transformers in the Calumet sub-station. The two blowers, each of which is driven by a Wagner 440-volt, 25-cycle, 7½-hp. induction-motor, are adapted to take care of all the transformers in the sub-station. The view also shows the low-tension distributing circuits, the portion of the switchboard comprising the 2300-volt feeder-circuit equipment, the lightning-arresters, and the apertures in the wall for the admission of the conductors of the 3-phase transmission line from the power station seven miles distant. The construction of the Wagner air-blast transformer presents several interesting features. As an example, attention may be called to one of the 13,200—2300 volt transformers above referred to, the air-passages are so arranged that the air is taken in at the bottom of the coils, and after passing upward through them it is forced by deflecting screens downward around the iron circuit, and is then discharged by a separate passage through the base of the transformer. The shutter in the base of the transformer may be so arranged that in the summer time the warm air may be discharged into an underground duct, and during the winter out into the air of the sub-station, for heating purposes. The transformers are of the shell-type, with pancake coil windings, giving a maximum cooling surface, and at the same time the best disposition of insulation between primary and secondary, and between coils and iron.

Self-Contained Dryer.

The accompanying illustration shows a dryer designed by the C. O. Bartlett & Snow Co., of Cleveland, Ohio, having in view the elimination of brickwork to the utmost possible degree, without sacrifice of heat-economy. Only the fire-box is bricked in. The dryer consists of two cylinders, one
inner and one outer cylinder. The inner cylinder is made taper ed, and is entirely self-contained. Near each end of the dryer are securely fastened cast-steel rings, or iron rings with cast-steel tires, resting on rollers or trunnions. There is also girt-gear with pinion and countershaft, and bevel gear with tight and loose pulleys. A fan is provided for cooling the furnaces, which start as fast as it is released. The operation of the dryer is as follows: The material to be dried is fed at the front end into the inner cylinder, and passes through the entire length of the inner cylinder, and then drops down to the outer cylinder. It is returned in this outer cylinder, thus traveling twice the length of the dryer, and thereby utilizing the heat to the fullest extent. There are inter-elevators for continually elevating and 'cascading' through the current of heated air. The products of combustion pass in the opposite direction, from that in which the material to be dried is traveling, taking up the moisture as fast as relaxed, and out through the fan into the stack.

Commercial Paragraphs.

Henry E. Egger, who since 1889 has been with McFarlane & Co., is now in the mining machinery department of the Mine & Smelter Co., Denver, Colorado.

The American Chemical Society announces that in January, 1909, it will start the publication of The Journal of Industrial and Engineering Chemistry.

The Denver Rock Drill & Mach. Co., manufacturers of the Waugh drills, have opened a San Francisco office at 405 Montgomery street. C. S. Wallace is in charge.

The Abbe Engineering Co., New York, announces that it has added a bolting machine and setting machinery department to its line of grinding and pulverizing machinery. J. M. Charles will have charge of the new department.

The Ore City Plant Iron Co., Ltd., London, advises us that it is in receipt of unusually favorable reports from the Randfontein installation of Ogle-Ridgway filters. The plant is treating 50 tons (dry weight) of 47% slime pulp per 24 hours, the power used being 5 1/2 horse-power.

The E. J. du Pont de Nemours Powder Co. recently entertained a party of operators from the anthracite coal fields of Pennsylvania at its Rapaua works, Gibbstown, N. J. A special train from Scranton carried the party to Philadelphia, from where they went by private yacht down the Delaware river to the plant. The method of testing explosives was explained and an elaborate series of experiments was conducted for the benefit of the visitors.

Catalogues Received.

The Jackson Machine Mfg. Co., Warren, Pa., has lately published a booklet dealing with gas and gasoline engines for electric lighting service.

The Jeffrey Mfg. Co., Columbus, Ohio, has recently issued Bulletin No. 13, which is descriptive of electric locomotives for industrial haulage.

The Fort Wayne Electric Works, Fort Wayne, Indiana, is distributing its Bulletin No. 1111, showing electric motor drives as applied to machine drills.

The Meree & Gottfried Co., San Francisco, has lately published Section 9 of its general catalogue, which is descriptive of button centrifugal pumps.

The Colorado Iron Works Co., Denver, has lately published its Cyanide Catalogue No. 109, which is a model in every respect. The catalogue proper is preceded by a short outline of the cyanide process, intended, as the introduction says, for those who are not familiar with its chemistry and technique. It is particularly lucid, complete, and concise. In the subsequent pages complete cyanide plants, machinery, tanks, and appliances are described, accompanied by adequate illustrations. The publishers of this catalogue have not made the mistake of using any ill-illustrating concer Rows, of slighting the quality of the illustrating material. The illustrations are all original and all good. An index adds much to the usefulness of the pamphlet.

Publications Received.

This is the annual compendium of the statistics, technology, and trade of the mineral industry as issued under the auspices of The Engineering & Mining Journal. Founded by R. P. Rothwell, and edited successively by the staff of our contemporary, 'The Mineral Industry' has won an assured position as a reliable authority. This volume is as excellent as its fifteen predecessors, and contains the customary reviews on the metal trades by such recognized authorities as W. R. Inglis, Frederick Hobart, and Floyd Parsons. Together with the retrospect on the literature of ore deposits and ore dressing, respectively, by Professors Kemp and Richards. Further comment is not needed. This volume maintains the high standard expected by those familiar with the book, and it remains only to refer to the fact that the editor has issued a circular letter stating frankly that the fifteen preceding volumes "have been published at a financial loss." The price of Vol. XVI is $10, and even at this price it must have active support in order to meet the heavy expenses incident to careful statistical work. This acknowledgment of financial difficulty is no surprise to those familiar with the enterprise, the cost of preparation, and the limited demand for such an expensive book. We would regret, as will the profession generally, if it prove necessary to suspend publication. A suggestion may be made: 'The Mineral Industry' should hereafter be issued from the office of The Engineering & Mining Journal, that is, it is part of the publishing activities of a company owning one technical mining paper. In days gone by when The Engineering & Mining Journal was the undoubted leader in technical journalism as applied to mining and metallurgy it was no handicap—but a help—to publish 'The Mineral Industry' by the aid of the same staff and by the help of the same contributors. It was possible to assume that 90% of the information available in America on mining and metallurgical subjects would filter through the pages of the New York paper, for in those days the technical papers in the West were of no consequence. Times have changed. Instead of one reliable journal devoted to mining and metallurgy, we have several on this continent, and it is a fact that a large proportion of the best contributions on technical literature do not go to New York. While we take pleasure in acknowledging the fairness and completeness of the references made by the reviewers in 'The Mineral Industry' to articles appearing in journals other than The Engineering & Mining Journal, we are constrained to emphasize the fact that 'The Mineral Industry' does not contain one-tenth of the authoritative comprehensive articles published during the year, and it will fail to do so long as it is the annex to a single mining paper. We would like to see 'The Mineral Industry' published on its own merits as the recipient of the best available material from all the mining papers, and as a compendium to which the editors of every mining paper could contribute gladly.—T. A. R.

This is the second edition, with additional matter. Most of Mr. Douglas's addresses have been abstracted in the Mining and Scientific Press soon after they were delivered, for we count them among the most thoughtful and informing of the general contributions to technical literature. We are glad to see that the demand for this reprint has warranted a second edition, and we hope that the accomplished author will continue to do further similar service as an educator. Our readers will find this volume a valuable addition to their library and a charming book to carry on a journey.

EDITORIAL.

A YEAR AGO we published a paragraph concerning the professional engagements of Messrs. Hammond, Butty, and Yeatman. Our contemporary in New York published a letter denying the accuracy of that statement. Anyone correctly informed concerning the facts today will find that we were either accurate or prophetic. We do not claim to be the latter.

IT LOOKS as if the Yukon fiasco had killed the Lawson-Guggenheim scheme to form a holding company for the Utah and Nevada Copper stocks. We hope this is a fact. Furthermore, we can state frankly that in our opinion the association of Mr. Lawson with the Guggenheim family has hurt their financial credit, not to mention their moral standing. The sooner Lawson is eliminated from mining the better for the industry; nothing but discredit can come from that gas manufacturer.

USUALLY it is more difficult to find ore than to choose a process of treatment, but, according to the statement of the chairman of the Company, the San Francisco Del Oro Mines, Ltd., has 325,304 tons, averaging 26 ounces of silver, 30 grams of gold, 12 per cent lead, and 23 per cent zinc. A dry process failed, but experiments with wet concentration look promising. The ore has a little too much of everything and not quite enough of anything, but if the sampling has been accurately done and the reserves carefully measured, there ought to be money in this ore, and we hope the Company will get professional advice that will result in a profitable realization of these assets.

ACCORDING TO accounts received by us, the Chattanooga meeting of the Institute was a well arranged affair. Capt. H. S. Chamberlaun was in charge and is to be credited with the excellence of the arrangements. Among the papers read was one by T. H. Aldrich, Jr., on 'The Treatment of the Gold Ores of Hog Mountain, Alabama,' the author giving interesting information concerning his work upon low-grade material. Messrs. Bureaud and Butts described the geology of the Birmingham district by the aid of a balky lantern. The papers of D. H. Newland and H. Foster Bain were read by title. Visits to the new dam, an important engineering undertaking, and to the Rockwood mines were much enjoyed. The weather was fine. The attendance included only 60 visiting engineers, but it was representative.

WE ARE PLEASED to chronicle the inauguration of a geological survey by the State of Virginia. That State ranks eighteenth among its sisters in the American Union in the value of its annual mineral production. It is splendidly endowed...
with resources in coal, iron, pyrite, zinc, and non-metallic minerals, and the prospect of developing a copper industry based upon the low-grade ores of the Virginia district is one that may be realized. That immediate attention will be given to a study of the economic geology of the State is a reasonable inference from the appointment of Mr. Thomas L. Watson, of the University of Virginia, to the post of director; ably assisted by Mr. J. S. Grasty of the Maryland Geological Survey. Following the wise lead of many other States, the home of the Survey will be at the University of Virginia, at Charlottesville, thus enabling it to utilize the resources in talent and equipment of a great institution of learning.

WHILE in disagreement with Mr. Hammond concerning professional ideals, we note several useful recommendations in his presidential address. One of them is the suggestion that mining engineers avail themselves of the assistance of local professional men when examining important mines in a district with which they are unfamiliar. Many bad blunders might have been prevented in the past by adopting this sensible idea, and much tribulation has been avoided by the few who adopted it many years ago on their own initiative. We referred to the matter recently, in our issue of September 12. In many districts the distribution of ore is affected by purely local conditions, concerning which a resident engineer is likely to have knowledge; without such knowledge, the examination and appraisal of a mine is apt to be a dangerous guess. Cobalt, Cripple Creek, Leadville, Goldfield, and Chihuahua are some of the many places in which a worldwide experience is likely to go astray, unless aided by some familiarity with geological conditions peculiar to the locality.

IN THIS ISSUE we publish the text of a speech delivered by Mr. Benjamin Ide Wheeler before the Trans-Mississippi Commercial Congress when in session recently in the city of San Francisco. As delivered, this utterance was an oration, both witty and inspiring; even now, in cold print, the address will be found rich in stimulating thought. The president of the University of California, like the Chief Executive whom he quotes, has caught the essential spirit of the breezy West and expressed it in manly fashion. Free air, wide spaces, elbow-room, and mental detachment—these are the dominant features of life in the West. But the most suggestive observation of the orator was the vivid contrast between the mental attitude of the early settlers on the Atlantic seaboard and their successors upon the Pacific slope. Here Mr. Wheeler struck a note that will vibrate in the heart and mind of the Western man. The people that developed the eastern half of this continent cast lingering eyes across the Atlantic, their faces were turned to the homes of their ancestry and their backs to the wilderness stretching far westward; but the men who made the West had cast off their ancient moorings, they had discarded the dreaming head and subjugated feet of Europe, they turned their backs to the long trail over which they had fought across mountain and plain; they faced the sunset; the Atlantic breakers sounded faint, the surf of the Pacific thundered a welcome. Beneath the sentiment is the fact; every year fixes it more firmly; the people west of the Missouri have learned that their life is no ante-chamber to another existence either in New York or Paris; this spacious land is their sufficient heritage. Their eyes have caught the glow of the setting sun, and in their ears is the song of the Pacific, bringing the promise of commerce with another East, the immemorial East that has become a new West.

THE INTRUSION of journalism into the precincts of mining finance is not new, as our friends in London and New York are aware, to their cost. In London there are fully 80 specimens of the gutter press thatatten on blackmail and backstairs criticism; they constitute a persistent tax on the revenues of the promoter, especially when he is vulnerable. In New York this type of prostituted literature is not so common, simply because people are less prone to take advice from irresponsible editors. But it appears that journalism can aid promotion in another way, more respectable and more insidious. Thus Mr. Julian Hawthorne, possessed of a name familiar to readers of light literature, becomes a director of a company that has stock for sale in a silver mine at Cobalt, Ontario. Mr. Hawthorne has—to use his own words—"dropped literature and taken up the development and exploitation of a mine." He sends letters to professors in universities and other people supposed to be easily lured by meritorious statements promising great wealth, such wealth as would enable a philosopher to publish his book, complete his research, or endow his alma mater. Mr. Hawthorne uses his ability as an artist in words to paint a verbal picture of a silver mine that is unlike any silver mine that ever was, a silver mine that rapacious capitalists are eager to take off his hands, a silver mine that will make the gold mines of Nevada look poor. Mr. Hawthorne and his associates want money to pay for additional ground. Do they ship some of the fabulous ore, do they sell some of their holdings to moneyed men? No, sir. They mean to keep the mine for themselves, they intend to dig their fortunes out of it, they purpose living on the dividends. So says that literary gent, Mr. Hawthorne. Therefore they write to professors who receive small salaries and to other people not wealthy, but possibly gullible. In proof of the value of the mine the intending investor will have the graphic presentments of Mr. Julian Hawthorne, "Author, Journalist and Historian," who is a director of the company that sells the shares, and the report of Mr. Woodford W. Brooks, the president of the company, who quotes "a few examples" of assays. The latter says that "there is no reason why an investment of a few hundred dollars should not return as much in dividends each year." We think that the probabilities are against it, and that the establishment of a literary bureau as an annex to a financial scheme is evidence of a desire to
"take up the development of a mine" in order to facilitate "the exploitation" of the public.

The Engineer as a Financier.

On another page we publish the address delivered by Mr. John Hays Hammond, as president of the American Institute of Mining Engineers, at Chattanooga, Tennessee, on October 1. We take pleasure in publishing this address because it is sure to interest our readers; it is the utterance of a man much in the public view and prominent of late in national politics; moreover, that distorting medium of misinformation, the daily press, has so magnified the salary and other sources of income of Mr. Hammond that his wealth has tended to obscure his position as a professional man, for in these days of reformation it is more difficult than ever for a rich man to enter heaven and a profit is without honor even on the stock exchange. To be frank, we do not agree with the thesis of Mr. Hammond's address; but that is no reason why our readers should be denied an opportunity of becoming acquainted with his views on professional ethics. We rate the utterance of a public man largely according to his sincerity: that is the touchstone by which most speech-making is found to be dross. Applying this test to the address of the President of the Institute, we find it 24 carat, for it is an apologia pro vita sua, it defends the code that has guided him in a remarkable career, it asserts the principles of conduct that regulate a group of men to whom it has seemed entirely proper to merge the engineer in the promoter. There is much to be said on both sides; we happen to take the view that participation in company finance undermines professional ethics and that personal speculation in mining shares saps the foundations of professional integrity, but that is the view of one person, possibly of more; at any rate, it is not the judgment of a court of last resort. And as against such old-fashioned ideas, there is much to be said. Mr. Hammond says it, and he says it well. "This is an era of expansion," therefore "the function of the mining engineer has expanded." His "limited usefulness" has gone beyond purely technical reports; he determines the "pecuniary relations of the enterprise" that he investigates. His opinion on geology must be supplemented by a commercial appraisal. Scientific investigation must proceed hand-in-hand with business management. As the mining engineer's field of activity expands, his code of ethics is distended. He does not face a theory, he becomes friendly with a condition. So run the introductory clauses of Mr. Hammond's address. Then he comes to concrete problems, and some of them are as hard as granite. What he says regarding reports made for the seller of a mine is excellent, but we are warranted in doubting whether it be the custom for engineers to state in such a report that it was prepared at the instance of the vendor; most vendors would object. If it be proper to state when a report is made for a seller, it is also proper to make a similar statement when the report is made for a purchaser; in other words, it would be well to make it clear on which side of the fence the engineer's legs are dangling; as a ladylike enrate once remarked in our hearing: "What is condiment for the male bird is also condiment for the female bird." Moreover, we are told that reporting for sellers is "undesirable work" for young engineers, because it places them in moral and professional "jeopardy." That is true; but it is also a fact that the young fellows are not always able to choose the task of examining mines for buyers rather than for sellers, and it happens that buyers usually select the older engineers to appraise their possible purchases. And this brings us naturally to the query: If young engineers are apt to over-value mines in the interest of the seller, are old engineers likely to under-value mines in the interest of the purchaser? Such things have happened. The code needs mending here. We could quote cases where engineers have taken pride in acknowledging an under-valuation that enabled their client to get hold of a mine for much less than it proved to be worth. The distinction between "fools" and "sinners" may be slight, as Mr. Hammond remarks, but the distinction between professional honor and commercial honesty still survives.

Next we come to contingent fees. Mr. Hammond's recommendations are excellent, but they are not such as are followed, as far as we know, by any large number of engineers. The idea of giving "full publicity" to "the nature of an engineer's connection" with an enterprise in which he has a contingent interest at the time of making a report, is commendable. We would like to see it put into effect. The first result would be to make prospectuses more interesting. As between payment in stock and payment in money, we see no tremendous difference, unless the stock be made non-transferable. Would not that proviso complicate the transaction to an irremediable degree? Do even engineers of the keenest ethical perception take stock with the idea of holding it indefinitely? Which position is "less vulnerable," that of the engineer who holds for a big price to be paid by a simpleton or that of the man who parts with his shares at a low price before the public has been fooled? To us this acceptance of contingent fees is an ethical tundra; it affords insecure footing and will land the moralizing wayfarer in a cold morass. Mr. Hammond's advocacy of "frank and full publication" of all questionable circumstances calls for hearty endorsement. But it would lead to rather lengthy reports. Even copious foot-notes might be required.

The mention of commissions on machinery and supplies seems almost an anachronism; we supposed such practices were unknown in these days of big salaries and fortunate participations. They belong to the period of small pay when it seemed a venial offence to make a little money 'on the side.' Not many engineers can have been subjected to the temptation mentioned. When it comes, the advice given by Mr. Hammond may be followed to advantage. But there is another complication that is not as rare as it ought to be, namely, the commission on the sale of a mine. Should an engineer
who makes a report on a mine accept a commission from the owner, or should he receive a bonus from the buyer? There also arises the question, by no means academic, whether an engineer is warranted in taking a commission from both parties to the transfer. We are aware of cases illustrating each one of these phases of professional—or unprofessional—conduct. Such transactions have been recorded in the archives of mining and it is fair to add that bad faith has not necessarily been imputed to those that were the beneficiaries. Commissions on machinery are rare nowadays; they are regarded as coarse bribes, and even when mitigated by the courteous exchange of a check to the credit of the engineer's client, they constitute a kind of business generally avoided. But the commission on the sale of a mine is a real evil concerning which the president of the Mining and Metallurgical Society of America should have something to say, because the president of the American Institute of Mining Engineers happens to have overlook it.

We endorse Mr. Hammond's praise of loyalty. An ounce of loyalty is worth a pound of cleverness. A professional man should remain loyal even when facing the disloyalty of his employer. *Noblesse oblige.* The engineer will "play cricket" in England and "play ball" in America even when his own side seems inclined to disregard the rules of the game.

The expert witness would be in less danger of professional turpitude if he could be labeled aright; we ought to call him a special advocate. He is not a witness in the ordinary sense of the word, he is a specialist who has espoused a cause and is prepared to substantiate a case by presenting observations and arguments for which he is paid. Usually he is prepared to fence skilfully with a cross-examining lawyer and to obfuscate the rudimentary intelligence of twelve farmers. Mr. Hammond quotes Dr. Raymond on this subject; it is fair to say that the association of the name of the secretary of the Institute has honored the avocation of the expert witness to such an extent that criticism of its anomalous duties seems futile. Yet we do not like to drop the subject without repeating a suggestion by no means new, namely: Let the Court select the experts who are to testify, or, if that be impracticable, let the parties to the suit agree on the selection of impartial scientific witnesses whose fees shall be paid on joint account. Then they would cease to be the advocates of one side, they would become unbiased counsellors to the Court and the jury.

Next we come to a large subject: The duty of the mining engineer to the investing public. The recognition of any obligation to the public can only come after complete fulfilment of the trust owed to the client. On the whole, we regard it as inadvisable for the engineer to keep his eye on the suppositions investors, for whom Mr. Hammond shows a proper solicitude. Charity begins at home; duties that are defined are apt to be recognized; it is difficult to serve the widows and orphans, the man on the street, and the rest of the flotsam and jetsam of humanity that gambles on the margin of stocks.

But the obligation to a client is specific, and being specific it may be hoped that it will be performed. By strict attention to the interest of his employer, the engineer is most likely to serve the welfare of those who accept that employer as their leader in mining speculation.

Mr. Hammond repeats the advice given by him several years ago to the younger engineers. He deems it well for them to become partners with the capitalists, to develop into promoters, to take a hand in the fascinating but dangerous game of mining speculation and company finance. He is consistent. We thought his advice pernicious when given several years ago in London, and we regard it as pernicious today when he gives similar counsel at Chattanooga. As well might an architect be advised to become a contractor, a practising physician to own a drug-store, a lawyer to form a partnership with the judge before whom he pleads, or a broker to speculate in stocks. The last affords the best parallel. A broker who himself speculates is a dangerous agent; his advice as regards the purchase and sale of shares is likely to be biased by his own dealings in them; his profit may prove to be the client's loss. He may know more about the stock-market than the detached middleman, just as an engineer who dabbles in promotions may be shrewder than the man who keeps aloof from such transactions, but where should the line be drawn? Must it be a line, or should it be a broad parade ground on which every kind of manoeuvre can be comfortably executed? Counsels of perfection are easily derided, but shall we pay any respect to counsels of imperfection? It is true, there are respectable brokers who speculate, and there are honorable engineers who buy and sell mines, promote companies to work them, and gamble in the shares. We do not undertake to make Procrustean rules for our professional brethren, but it is necessary for the president of the Institute to recommend participation in a game that at best is tricky and at its worst is fundamentally unprofessional? We state the case strongly in order to offset the effect of Mr. Hammond's frank justification of the commercial activities that have yielded an immense fortune to himself and his friends.

Mr. Hammond disclaims authority for his remarks, and modestly denies that he is offering "an official and representative declaration of principles." At the risk of seeming discourteous, we insist that this is just what he has done, for he speaks as the president of the Institute. Hence the serious attention we give to his utterance. Moreover, whatever he has to say on these matters is given weight by his political prominence, his undoubted fame as a financier, his unquestioned successful application of the principles he advocates. We deem them contrary to the best interests of the profession. A promoter may "in a high and worthy sense of that term" be a good citizen, not infrequently the community owes much to his initiative, but his essentially commercial code cannot be grafted upon any professional ideal without bringing forth fruit of a highly variegated character.
### Personal.

**Henry Bratby** is here.

**Albert Burch** is in Mexico.

**W. P. Hammon** is at Boston.

**Frank W. Olfield** is in Arizona.

**R. H. Campbell** has gone to Seattle.

**Edgar A. Whitney** is in San Francisco.

**H. H. Web** is here, on his return from Mexico.

**Charles James** was married at Berkeley on October 7.

**L. T. Hoyle** has returned to San Francisco from Colombia.

**George W. Maynard** has been examining mines in Colorado.

**S. F. Shaw** will be at Bodie, Cal., during October and November.

**James S. Wyatt** is inspecting possible dredging ground in Wyoming.

**Richard A. Parker** has returned to Denver from New York and Boston.

**William A. Heywood** is expected in London upon his return from Chile.

**William Forstner** is examining oil lands in the Coalinga district, California.

**F. F. Sharpless** was at Kansas City last week, on his return from Sonora, Mexico.

**Alfred von der Ropp**, who now lives at Geneva, in Switzerland, is in San Francisco.

**J. S. Camp** has opened an office for engineering and surveying at Cottage Grove, Oregon.

**J. P. Fox**, former superintendent of the North Pole mine, at Bourne, Oregon, has moved to Seattle.

**A. Chester Beatty** has been making a tour in Arizona and Utah, with Charles Hayden, of Hayden, Stone & Co., Boston.

**Benj. B. Lawrence** returned recently from Cobalt, Ontario. He is consulting engineer to the Kerr Lake Mining Company.

**A. Van der Naillen**, of the School of Practical Engineering, at Oakland, left on October 3, on a journey to Europe. He will be absent four months.

**Cornelius E. Palmer** left New York on the 12th inst., upon a tour of inspection of Pinguino, Peregrina, and Mexican Mining & Transportation Co. properties, at Guanajuato, Mexico, and of the Esperanza property, at El Oro.

### Obituary.

**John Edgerton Haworth** was stabbed to death on September 24, by a workman discharged by him as manager of the Ponderosa mine, in the Province of Huesca, Spain. He was a man with an honorable record as a mining engineer in many countries, and an associate of the Royal School of Mines. His tragic death will distress many friends.

**A. Arthur Abbott**, a graduate of the Houghton School of Mines (class of '93), died at Bellevista, near Caliho, Peru, after a short attack of chagrin. Previous to going to Peru, he had practiced in California, Montana, and South Dakota. In Peru he was first employed with the Cerro de Pasco Mining Co., leaving their employ; as superintendent of mines, to engage in private work. At the time of his death he was consulting engineer for the Peruvian Mining, Smelting & Refining Company.

### Dividends.

On October 26 the Homestake Mining Co. will pay its monthly dividend of 50 cents per share on a capital of 215,400 shares of $100 each.
General Mining News.

ALASKA.

W. J. Bowen, of Seattle, has purchased the mining property belonging to Harry Dobson, of Ketchikan, on Glacier creek, Portland canal. The consideration is $9,000, the first payment of $100 has been made. —The Gold Run Ditch Company has recently found rich gravel on the left limit of Gold Run, opposite No. 8. It is a well-defined old channel about 2½ ft. thick which pans from $10 to $30. —The latest reports from the strike made by Dolan & McFadden on the Upper Kougak are to the effect that it is even richer than was first believed. The strike is at least 30 ft. wide. —It is reported that O. C. Mason and Frank Pearl have made an important strike on Glacier creek, in the Candle district. —Howard Ames is at the head of a scheme to put a number of dredges on the tundra between Sunset creek and Penny river.

ARIZONA.

CILA COUNTY.

The Baldwin Syndicate of Chicago, represented by G. T. Harrington, has purchased a group of 15 claims in the Lost Gulch district, near Globe. The purchase includes the E. F. Keller group on which there is a five-stamp mill. The purchase price is not made public. Mr. Harrington has gone to Chicago to organize a company and on his return to Globe will start work and probably re-construct the mill and add new machinery.

GRAHAM COUNTY.

It is said the Copper Queen has had a corps of engineers and assayers at the property of the Ash Peak Mining Co. investigating the property with a view to purchasing. Needless to say all the people of Duncan and vicinity are pleased with the prospect of the Queen entering this field. —The new machinery, including a big air-compressor and station-pump, has been installed at the Fumarole mine near Safford and is now in operation, and sinking has been resumed in the double-compartment vertical shaft. Several months ago sinking was stopped and all the men put on driving and cross-cutting on the 500-ft. level. The drift on the vein has exposed the orebody a distance of 180 ft. Two cross-cuts have been run 45 ft. each way, without reaching the wall. From the drift a winze has been sunk to a depth of 50 ft., at the bottom of which there is ore assaying about $7 in gold. It is believed that operations on the erection of mills will be commenced within the next two or three months.

MOHAVE COUNTY.

Morgan J. Jones has taken a contract to sink 100 ft. on the Gold Bar mine, at Cerbat, which was recently taken over on bond from T. R. Gariner by J. A. Elway, of Philadelphia. —The shaft on the Pittsburg mine in Crow canyon has reached a depth of 100 ft. and a cross-cut has been started. The new pumping machinery is on the road and some of it has already arrived at Yucca. The plant will have a capacity of 100,000 gal. per day, and when it is installed the shaft will be sunk to the 500-ft. level. —It is probable that the Pittsburg company which recently took over a group of claims on Big Williams Fork, belonging to Sam Butler, will start work at once. A new hoist has been purchased and the shaft will be sunk from its present depth of 60 ft. to the 1000-ft. level.

YAVAPAI COUNTY.

Development operations on a larger scale than ever before will be started soon on the properties of the Black Mountain Copper Co. in the Mineral Point district. As soon as the new hoisting and air-compressor plant is installed the sinking of a new shaft will be started. Part of the machinery is now on the ground and the remainder of it is on the way to the camp from the factory. —Seventy men are now employed on the Monaca mine, 13 miles south of Kirkland, the average daily shipments to the smelter being 20 tons. Stopping is being pushed on the 600, 600, 800, and 900-ft. levels, with good showings in every heading. A 50-lb. gold bar was recently shipped through the Bank of Arizona, being the product of a clean-up at the cyanide plant. The property is now being operated by C. E. Bunker, who is receiver under bankruptcy proceedings.

YUMA COUNTY.

The management of the Corona Copper Co. has purchased a hoist for its property, 26 miles northwest of Wenden, and will deepen its working shaft which is now down 400 ft. Three more will be worked and an adit, now in 800 ft., will be pushed forward. S. A. Butler, superintendent, of the Company, has recently returned from Pittsburg, where he secured ample funds to carry out the elaborate plans of the concern.

CALIFORNIA.

BUTTE COUNTY.

The owners of the Francisco mine, near Enterprise, have ordered a 50-hp. gasoline hoist and arrangements are being made for the purchase of a 20-stamp mill. An adit 600 ft. long has been driven to the vein, the assays of which are not made public. It is this mine in which Eugene Schmitz, former mayor of San Francisco, is said to be interested. —It is reported that Ed Morse has found rich gravel in an adit on his placer property on Little Butte creek, between Centerville and Paradise. One $140 nugget was found and the material contains much coarse gold.

INYO COUNTY.

The Inyo Coso Co., a Portland, Oregon, concern, is putting in a 2-in. pipe line 3½ miles long from the Howard springs to its group of claims about 17 miles south of Darwin. A small mill will probably be built in the near future. Considerable development has already been done and good ore is exposed in a number of places in the property.

NEVADA COUNTY.

(Special Correspondence). —A shoot of rich ore has been cut in the west drift from the bottom level of the Golden Gate mine. It is intended to install a 10-stamp mill and an electric power plant at an early date. Charles Hobbs, of San Francisco, is manager. W. P. Martin is superintendent. —The water famine is causing considerable trouble in the Grass Valley and Nevada City mines and all of the properties are laying off their employees. The Empire mill is working at a small force, and the Pinehill, Miner, and North Star group are operating with the aid of steam, but it is likely that the latter properties will be forced to greatly reduce operations in the near future. —Machinery for the mill at the Birchville mine is arriving and will be immediately installed. Active underground work is progressing. —The Muller & Walsing claim in Woods' ravine has been bonded to J. P. Lane, of Goldfield. An incline shaft will be sunk on the vein and considerable development work commenced.

Grass Valley, October 12.

SAN BERNARDINO COUNTY.

Work has been started on the Flyer property and shipments will be started to the Little Giant mill at Hart. A bunk-house is being erected and the existing 30-ft. shaft is being sent down. Milton Munday is owner. —The foundations of the Little Giant mill are being re-built and the plant overhauled. A rook crusher has been ordered and it is planned to operate the mill continuously hereafter. William L. Foster is superintendent.

TUOLUMNE COUNTY.

Work is to start soon at the Sweeney mine, which has been the subject of litigation at irregular intervals for over a quarter of a century. The shaft will be cleaned out and re-timbered and a new hoist put in. The property is owned by C. H. Segerstrom and George U. Hind, the latter of San Francisco. —Calvin F. Summers has bonded his mine, the Contention, in Jupiter district, to A. C. Morrison. The contract price is $39,000. —Work was stopped at Excelsior mine last week pending the installation of a
MINING and SCIENTIFIC PRESS
October 17, 1905.

pump to handle a large inflow of water recently encountered. —Operations have been resumed at the New Albany; water is being secured for the mill. —A portion of the Santa Isabel has been leased to C. K. Kelly. He is preparing to begin work. —T. G. Wilcox, of Oakland, has purchased the Seminole mine near Araratville. The consideration is $35,000, of which one-half must be paid before August 5, 1909, and the remainder before January 5, 1910. The terms of the contract require the active operation of the mine, beginning at once. The management of the Norton, at Big Oak Flat, has decided to cancel all leases and develop the mine on company account.

COLORADO.
CLEAR CREEK COUNTY.
(Special Correspondence.) —The bond of $29,000 on the Smuggler property, on Brown Mtn., was lifted this week by the Main Gulch M. & M. Co. Operations are being carried on through the shaft, which has been sunk to a depth of 300 ft. Levels have been run from each 75-ft. station and ore streaks exposed that vary from one to two feet wide. It is the intention of the manager to start sinking at once, as the ore-streaks are known to extend to great depths. A number of lessees are at work, and all are stopping or driving on fine bodies of ore, the average content of the product being in excess of $100 per ton silver and lead. Conti & Co. are sending out regular weekly shipments, while Stevens & Co. are breaking about five tons per day. As soon as the sinking of the shaft has been completed, drifts will be run, at which time new leases will be granted.

Shipments from the Terrible mine, on Brown Mtn., continue and the output during the present year promises to exceed that of any period in a long time. The ground is being operated principally by lessees, operations being centred on both the 11th and 14th levels. It is reported that in the near future development will be started on company account. The 11th, 12th, 13th, and 14th levels are to be cleaned out and remultiured, while the drifts will be extended to Dunderberg ground, which is an extension of the Terrible vein. B. C. Catren, of Georgetown, is manager. —E. K. Cass and John O'Dea have taken a bond and lease on the Star group of four patented claims in the Peru district. The bond calls for $10,000 and runs for two years, the first payment of $1000 to be made April 1, 1909. Work has been put under way, and shipments are promised for the near future. In the breast of the adit there is exposed a 12-in. streak of silver-lead ore that is worth more than $60 per ton. Cass & O'Dea also control a group of 21 claims in the same vicinity and both holdings are to be consolidated. A company is to be organized at once. —The Ruby Argentine M. & M. Co. has advanced the Calia adit past the 1900-ft. point, five veins having been intersected. It is expected that the Calia vein will be reached within from 50 to 75 ft. —Work is to be resumed in a few days upon the holdings of the Atlantic M. & M. Co., operating a large group of claims in the Atlantic district. A. A. Ireland is manager. —Work was resumed this week upon the holdings of the Charter-Raton M. & M. Co., after a close-down of four weeks. Driving has been started on the Charter vein, cut 47 ft. from the portal of the LaMome adit, a side adit of medium grade ore being followed that is from 6 to 8 in. wide. J. J. Bonner is manager. —A heavy tonnage of ore is being mined from the Sun and Moon, operations being centred on the 12th and 17th levels. The 15th level has just been started and soon work will be started on the 13th. R. C. Bonney, of Idaho Springs, is manager. —J. Humphrey has taken a bond and lease on the Amason and Crenous claims, on Seaton Mtn. Work is to be started at once. These veins are on the line of the Idaho adit and will be intersected within the next few months. —A plant of machinery, consisting of a gasoline engine, air compressor, and motor, is being installed at the Merry Monarch adit, in the Alice district. The bore has been advanced for nearly 600 ft., two veins having been passed. J. W. West, of Alice, is manager. —Work was resumed this week in the driving of the Burns-Moore adit, on Chicago creek. Work will be carried on as long as the quality of water is available.

The Humboldt mine, on Ute creek, is undergoing development by Dominick Polaris. An ore-shoot 75 ft. long was recently passed, and free gold is in evidence. Stoping is to be started and a steady tonnage of high-grade ore will be marketed.

George-town, October 16.

LAKE COUNTY.

The work of repairing the plant at the Ruby property at the head of Iowa gulch has been going on for some time and development work will be carried on all winter. — Howard Collins, manager of the Anova property, has arranged to operate the old Gypsy mine, adjoining the Anova in Iowa gulch. The Anova has maintained steady operations since early last spring, and the work there has met with more than favorable progress. The Gypsy is to be operated by Eastern capitalists, but Mr. Collins will manage it in connection with his other work. It is expected that the ore streak that has been found in the Anova will also be opened in the Gypsy. Both the Anova and Gypsy will be operated by electricity, the Anova having been supplied with power since it was opened last April. —Dennis Nelson reports a strike of $75 ore in the adit on his Emerald group in Delmiscon gulch.

OUFAY COUNTY.

Brown & Barker have found four feet of high-grade copper-silver ore on the Keno claim in Grey Copper gulch near Ouray. The claim is owned by Pierson & Bradley. It is claimed that the ore contains 40% copper and 60 oz. silver. —Work has been stopped on the Young & White claims on the Charn property in accordance with instructions from the owner, Robert H. Lucas. It is reported that a party of New York capitalists are trying to buy the Mineral Farm. —George S. Reed has purchased, for the Mine & Smelter Supply Co., of Denver, the Barstow mine in the Red Mountain district. The property consists of 26 claims and a mill-site, and is equipped with a 20-stamp mill, electric hoist, a compressor plant, tramway, ore-bins, and numerous accessories. It is believed that the new owners will open the property next spring. —As a result of a drilling in a missed hole at the Treasury adit, one Italian was killed and two others seriously hurt last week. The fault was with the preceding shift in reporting that all holes had been fired.

SAN JUAN COUNTY.
The affairs of the Gold Prince Co. have been settled by the appointment of a receiver and work will be started again. —A second shift was put on last week at the Gold King mine. The new power plant is practically completed, and a larger force will soon be working than before the disaster last June. —The Ross Mining Co. last week started active operation on the Champion property, on Sultan Mtn., starting with 25 men. The ore will at first be shipped to some outside smelter. —Two shifts are working on the Iowa-Tiger, giving employment to 45 men at the mine and 15 at the mill. The Company is shipping one car per day to the Salida smelter, and this record will be kept up indefinitely. The Company expects to work all winter and preparations to this end are going on.

IDAH0.

COEUR D'ALENE COUNTY.

Increased activity is reported throughout the Boise basin. The Golden Red mine, four miles northeast of Placerville, is treating 40 tons per day in its own mill and has a large ore reserve opened up. The ore now being treated assays about $7 per ton. The process is amalgamation followed by cyanidation. A new 300-ft. double-compartment shaft has been started and extensive development will be done at the 300-ft. level. P. A. Meldinger, of Chicago, is president of the company owning the mine.

IDAHO COUNTY.

Two veins of free-milling gold ore have been struck at the Hope property in the Elk City district. One measures five feet and assays $41; the other is two feet, assaying
MINING and SCIENTIFIC PRESS October 17, 1908.

more than $30. The property is under bond to Philadelphia and Atlantic City capitalists, with option to buy the South Fork property in the same district. Hunter Supplee, who has charge of development work, is moving the Espey mill from the South Fork property to the Hope. —Work has been started at the Elk mine on the south fork of Clearwater river and will not be started again until spring. Carter Bros., the owners, have sunk a 100-ft. shaft and driven a 55-ft. cross-cut to the ore. —Three feet of carbonate ore assaying 15% copper and carrying $2.60 gold and 7 oz. silver per ton, has been cut at a depth of 60 ft. in the Chicago claim in the Rapid River district. The strike was made at the end of a 90-ft. cross-cut. Salt Lake people own the property. —Work will soon be resumed on the new trail on the south fork of the Clearwater river, to connect Orogrande and Harpster, an. it is the intention to have completed this trail, driven by Shadduck, of Spokane, has taken a bond on the Carpenter & Wilson group of claims on Four Mile creek, in the Orogrande district. The consideration is said to be $80,000.

OWYHEE COUNTY.

W. H. Waldron, of Boise, has made the first payment on the Stuben and Ontario property to Sullivan & Matheson, and the company which he represents will start a force of 10 to 20 men at once. This is the same company that is driving the adit to cut under the Weston, Village Blacksmith, Rubi, and Owyhee claims on War Eagle Mtn. —The tube mill and Willeys for the Potosi have arrived and the plant will be ready to run before long. A body of good ore has recently been cut in the south drift on the 300-ft. level, and prospects for the property are bright. —The mining men and merchants of Silver City have formed a Commercial Club to advertise the camp and promote the interests of the community.

SHOSHONE COUNTY.

(Special Correspondence).—Many interesting developments have marked the last week's progress of the mining industry in the Coeur d'Alene, among which perhaps the most significant is the firing of the first gun of the local battle between the Federal Mining & Smelting Co., the Coeur d'Alene branch of the American Smelting & Refining Co., and the Bunker Hill & Sullivan Co., the world's greatest silver-lead producers. For a long time past rumors of this great suit have been current in this district, but it was only the other day that matters finally came to a head by the filing of two suits in the Federal Court by the Federal company, with the object of quieting title to orebodies within the plane of the end-lines of the Overlap and San Carlos lode claims. According to the statement of the attorneys representing the Federal company, an accounting will be demanded of the owners, ore already taken from the disputed ground, but no restraining order will be asked for. The plaintiff company claims to have the apex of the orebodies. It is impossible to obtain any estimate of the value of the ore in dispute, but it is certain that the suit will be the biggest of any kind ever tried in the State of Idaho and will rank high among the biggest mining suits of the world. The next meeting of the Federal Court was held at Moscow November 16. —The Bunker Hill & Sullivan Co. declared its regular monthly dividend of $75,000. This is the 133rd dividend paid by the Company and makes a grand total distributed by the mine under its present management of $10,515,000, or which $705,000 has been paid this year. —The whole Coeur d'Alene district has been stimulated by the announcement by the Snowstorm Mining Co. to the effect that the Company will discharge a dividend at the rate of three cents per share October 20 to all stockholders of record on October 10. No announcement has been made as to whether or not future dividends will be paid monthly or quarterly. —The affairs of the Rex Mining Co., which have been considerably tied up by litigation for some time past, look as if they might gradually straighten themselves out. This has been aided by a recent stipulation of the attorneys engaged in the different suits to the effect that the mine may ship during the litiga-

The Coeur d'Alene, Idaho.
highest-grade ore ever shipped from the Coeur d'Alene was taken some time ago.—A power line from Thompson Falls, In Montana, to the mines of the Murray district of the Coeur d'Alene has been successfully financed by Ed Donian, of Missoula. The cost of this plant will be between $2,500,000 and $3,000,000, and it is believed that by this means power can be supplied to all the mines of the Coeur d'Alene. The power plant itself will be approximately 31 miles long, and from the Summit district a branch will be run to the Wallace district. At the driest seasons of the year it is believed that not less than 29,000 hp. can be obtained. The right of way for the line and its branches has already been secured.

Wallace, October 10.

Missouri.

Jasper County.

(Special Correspondence).—The Lucky Jim Mining Co. has completed its new mill and has started operations. The plant will handle 300 tons per day and is the third large plant to be built in the vicinity within the past 18 months. The others are the Bull Frog and Nortonia. The ground at the Lucky Jim has been well developed and the plant can be kept steadily running. The ore deposit is the same as is worked by the Bull Frog, a high-grade zinc-blende.—The Tidoute Co., operating in Turkey creek bottom, will build a large concentrating plant soon. The Company has a 25-year lease covering ground previously, although the mineral supply is far from exhausted. The shaft is now down to 40 ft. and weekly turnings are being made. The orebody continues to 75 ft. as shown in adjoining properties. The old Keystone mine in one corner of this lease has been sub-leased and the ground is being drained preparatory to re-opening.—A number of companies are preparing to re-open their properties or to start development on prospects tracts. The Meadville Mining Co., which last year built a large concentrating plant at Porto Rico, will resume operations. The present shaft is being doubled in size, as it was inadequate to furnish the mill with ore. Galena is the chief ore mined and this occurs in a sheet formation at 130 ft.—Work will be resumed at the Emperor mine, on the Grogg land south of Joplin. A 156-ton mill is on the lease and a shaft is down 145 ft. in good galena and zinc-blende. The property has been closed several months, but no serious difficulty is anticipated with water as only a small amount has accumulated in the drifts.—W. J. Briggie will open a 20-acre lease on the Luke & Ash ground, west of Joplin. The tract has 11 drill-holes and a shaft in a good sheet of ore. A new shaft has been started on a drill-hole which was unusually rich, the assays averaging nearly 15% copper. A soft deposit of zinc-blende was discovered just above the sheet ore.—The incline shaft at the Tennamani mine, west of Joplin, has been completed. The mouth of the shaft is near the mill, while the bottom penetrates virgin territory. The shaft is 6 by 8 ft. and slants at an angle of 45°. It is 242 ft. long, though the ground is worked at the 185-ft. level. Two-ton skips are installed for hoisting. The former vertical shaft near the mill will be used for ventilation after being condemned by drifts with the new incline shaft.—Throughout the district a tendency is noticed toward developing the lower levels which were formerly unknown, the shallow deposits only having been discovered. Drilling the past year has been very successful in opening up these lower runs, which are in many cases much richer than the shallow levels. The General City, which has been operating steadily for some time and which is distinguished as being one of the few properties in the sheet-ground district to keep at work without interruption during the panic, will go to work developing the lower runs of ore. The Company has been taking the ore from the 165-ft. level, but the shafts will be lowered to penetrate the deeper runs. The rich deep deposits at Orongo on the Hill Top lease will be developed by J. H. Tomlin and associates. The tract has been thoroughly drilled this past summer and the existence of a rich deposit of sheet ore lying at 230 ft. demonstrated. The deposit is the same as found in the Orongo Circle No. 5. Some shafts are already down a considerable distance, though none are in the orebody. The pumps are being operated through these shafts.—The Diamond Jack Mining Co. has sub-leased its mine to John Kinnmouth and associates, who are taking up the development work. This is an old property and from the shaft over $300,000 has been taken. The Company has sunk a drill hole near the former shaft and penetrated a 30-ft. face of rica galena and zinc-blende. It is probable that much ore still remains and the Company will develop the tract at once.

Joplin, October 10.

Nevada.

Douglas County.

The work of erecting the stamp-mill on the property of the Pine Nut Con. Co.'s claim near Gardnerville has been progressing rapidly, and now the stamps are in readiness for the initial run. The boiler, engine, and other machinery have been set in place and the mill-building is now under way. The pump which will lift the water from the shaft will probably be installed next week.

Humboldt County.

It is reported that a rich strike has been made on the Wihuja lease on the Therien property in Seven Troughs canyon. An 18-in. streak of ore has been opened between the 200 and 265-ft. levels, the assays of which will compare favorably with the richest ground already removed. The new Signal Peak Mining Co., whose property occupies the high divide overlooking Seven Troughs canyon, will make its first shipment of ore the latter part of this month.—The old Espee mine, about two miles west of Chaey, which was worked during the sixties and seventies for silver and which has been idle for many years, has been re-located by A. J. Jefts, F. E. Sullivan, and Mr. Davis, and they, together with E. P. Nancey, have in the past month won a 10-ft. shaft, which contains three claims, into the Chaefy Gold Mining Co. Only two miners are at work, but the new Company plans to begin active development soon. The ore remaining in the old working carries mostly gold.

Esmeralda County.

The Grutt Hill Truitt Co., of Rawhide, has cut the Coalition & Mint vein, at a depth of 50 ft., which at one point is 18 in. wide and averages $217. At the face of the drift four feet of ore averages $67.—The Southern Pacific is preparing to resume traffic over the old narrow-gauge railroad between Mina and Candelaria which has been abandoned for a period of five years. The road was constructed during the boom days of Candelaria, but when that camp became quiet and its mines apparently worked out, the road was abandoned. Several properties at Candelaria and in the vicinity have now opened and the companies promise sufficient tonnage to operate trains, so the railroad company will accordingly renew the service on the line. It is planned to have the line running about the last of October.—A second shaft has been put to work in the Gotwaldt Combination lease and the big vein on the 315-ft. level is being developed. Stock in this Company was listed several days ago.—It is probable that the shaft in the Muhett lease will be sent to greater depths. A winze for determining the expediency of this plan is now being dropped from the 490-ft. level. The entire bottom of the winze is in pay ore.—The mines of Goldfield produced during the week ending October 10 a total of 1950 tons, estimated to be worth $154,425. During the same period the Tonopah mines produced a total of 5626 tons, of an estimated value of $143,800.

Lincoln County.

A larger Cornish pump has recently been put in the shaft of the Quartette and the management plans to sink below the 10th level. Thirty stamps on the mill are dropping, the 150-ton cyanide plant is running to its full capacity and 100 men are on the pay-roll of the Company.

T. H. Tracy, of Los Angeles, recently passed through
Searchlight on his way from the camp of Capitol. The conditions are said to be exceedingly favorable and a 10-ton launch is to be put up at once. The Company is building a 10-ton launch on the Colorado and the machinery will be towed up on a barge.

**Nye County.**

A sufficient supply of water has been secured by the Keane Wonder to run the mill full time, which will very materially increase the production of the mine. Hitherto the Company has always had to contend with a water shortage, rendering it impossible to run the 20-stamp mill full capacity.—With plenty of ore blocked out in the mine to keep its 100-stamp mill running to full capacity, the Tonopah Mining Co. is devoting a great deal of energy to the opening up of new veins for the prospecting for others. The new work is being carried on throughout the Mizpah, Silver Top, and Red Plume claims of the Company, and drifts and cross-cuts are being sent out on every level from the 200 to the 600-ft. During the past week a total of 584½ ft. of new ground was broken.—The Manhattan Home Leasing Co. has been organized by residents of Manhattan to engage in mining. The Company will be incorporated with a capital stock of $15,000, of which $4.75 per share will be offered for public subscription, and payments will be accepted in monthly installments of 10%. It is proposed to sink the 200-ft. shaft now on the Briggs-Evans lease, at least 300 ft. deeper, and to also ship the ore that is already blocked out in the upper levels.

**Washington.**

**Ferry County.**

(Special Correspondence).—The Keller & Indians smelter will blow in about November 1 with a reserve of 1500 tons of ore in its bins. Teams are now piling up the reserve, as the Manila mine and other small properties that will supply it cannot furnish the full amount daily. The plant will treat 100 tons per day. This is the first time any attempt has ever been made to put the plant in shape, and the first time actual returns have ever been probable. Keller is 25 miles from a railway, but a steamer up the Columbia, which will make three trips a week, will now handle the matte produced.—The lessees of the Republic mine have renewed their option to J. L. Harper, who has gone East with S. H. Manly to get capital for purchase and development.—A strike of splendid looking high-grade silver-lead ore has been made in the adit on the Summit claim of the Colville Mining & Smelting Co., at Park City camp. Specimens of the ore were shown me by Capt. Hanford, of Seattle, who has been inspecting the Mountain View and other mines in that camp. He says the vein is eight inches wide and is considered to be a stringer, the main vein not yet having been cut. Ten men are engaged on the erection of the Company's smelter.

Republic, October 10.

**Stevens County.**

(Special Correspondence).—The First Thought Gold Mines, Ltd., is preparing for extensive operations, and has ordered a standard air-compressor plant, engine, and a diamond-drill outfit. It is intended eventually to use electric power, and the compressor plant will be arranged with that end in view. The working force is being largely increased, expecting to double the present output. The Company owns nine patented claims and intends exploiting its virgin ground thoroughly in various places. Both the Northport and Trail smelters are now receiving First Thought ore.—In the North Star mine, the south extension of the First Thought, a large body of free milling gold ore has been developed at a depth of 150 ft. The ore assays from $9 to $20 per ton across 80 ft. of the vein. A trial shipment of a carload of ore will be made soon.—Ore assaying as high as $43,000 is reported to have been struck in the upper workings of the Beecher mine, in constantly widening stringers. The Company is sorting the ore and expects to make the first carload shipment in a few days.—Eastern capital has been secured for the Mc-Kinley group of claims in Pierce Lake district, and development work has been resumed.—It is reported that the old Acme mine, five miles south of Kettle Falls, has been bonded to the British Columbia Copper Co., of Boundary Falls, B. C. Several years ago the Northwest Mining Co. had an adit 1300 ft., but without expected results. The surface indications were the inducement for the new deal. The consideration is reported to be $50,000.—In Che-welah district pipe is being put in the Jay Gould mine, for a steam-driven Burleigh drill to be used on the 175-ft. level. A mine has been sunk 30 ft. from the 100-ft. level and is in a fine quality of ore. A blind lead was struck on the 160-ft. level which proved to be about 25 ft. wide, the ore assaying about $3 per ton.—Work has been started on the Three Sisters mine, a new copper property near Chewelah. The vein outcrops for a distance of about 400 ft., and is 20 ft. wide.—The first annual meeting of the Silver-Lead Mining Co. was recently held at Newport. The officers elected were W. E. Wettzin, of Cement, president; J. H. Long, secretary, and D. Caldwell, treasurer.

The Company has done considerable work and developed a five-foot vein of lead oxide ore, which assays 35% lead. The Company has funds on hand for further developing its property.—The Blakely mine has about 140 acres of ground near the Pend d'Oreille river, 3½ miles north-east of Newport. A large quantity of gold and copper ore has been blocked out. The No. 1 adit, driven 250 ft. on the vein is all in ore. The main adit, 575 ft. long, has been re-timbered and a cross-cut 100 ft. from the face has cut through fine looking ore. After a few months further development the Company will begin shipping ore.

Orient, October 9.

**Chelan County.**

(Special Correspondence).—The Washington Electric Mining Co. has a well-developed property at Blewett, 16 miles south of Leavenworth, in the Mt. Steward district. This district is drained by Pechastin creek, that flows into the Wenatchee river. The Company has locations that cover more than a mile of the strike of a quartz vein which runs through a serpentine country. Former owners did several miles of work in the shape of adits and drifts, and this Company, under the superintendency of E. C. Limbach, drove a working level 100 ft. lower than any of the old workings and made a raise connecting them. The length of the new adit level is 1500 ft. A shoot of ore has been opened on the lower level, and the one above it, the raise between them being in ore. It is stated that the orebody thus opened ranges in width from 2 to 18 ft. The ore consists of quartz carrying free gold and iron sulphide that runs high in gold. An aerial tramway, 800 ft. in length, was erected by former owners to carry the ore from the mine to the mill. The latter is equipped with 30 stamps, plates, vanners, and cyaniding facilities, the machinery being run by water power. The intention is to start the mill later.

Leavenworth, October 10.
Special Correspondence.

LONDON.

Cornwall is just now experiencing disappointment. The greater demand and higher price for tin of late years, together with the supposed improvement in methods of mine-drainage and ore-dressing, were regarded as the commencement of a new era of prosperity for the Duchy; but things have fallen so lamentably short of anticipation as regards the vaunted superiority of methods that business is far from being cheerful, even though black tin still stands at the respectable level of £30 per ton. This may well be regarded as a matter for surprise, seeing that a good deal of capital has so recently been spent in development, and that some of these mines lived through the stress of a time when tin was at less than half the present ruling price. The Dolcoath shareholders have had to forego their usual dividend for the last six months, and a set-back is felt in tin mining generally in the county. One hears little of new mines, tin-plate schemes, or anything of that sort in the county, for some four or five years ago. Some have been abandoned or suspended, and others are not yet in working order, mainly, it is said, through failure to get results from the electric plant. There seem to have been sad errors of judgment somewhere on the part of the promoters, seeing that electric pumping has so long been successfully practised elsewhere. This matter—this fiasco, it may be said—was much talked about last month during the meeting of the Polytechnic Society of Cornwall at Camborne, but the discussion seems to have left things much as it found them. It now remains to be seen whether, in dealing with heavily valued mines, the electrical pump will not be discarded in favor of the old arrangement with the direct-acting steam engine, which, though more cumbersome, seems after all to be cheaper. Electricity, in spite of the recent difficulties, will eventually be applied in Cornish mining, the power being generated in the nearest coalfields. Great things were promised, too, in certain quarters by more modern methods of concentration, particularly of tin slime, and in dealing with the "balanos," and the dumps of the old mines. There has been liberal outlay and no end of experiment, but nothing brilliant in the way of result. The present situation presents a problem that seems as far from solution as ever.

A few weeks ago I mentioned that the old firm of Williams, Harvey & Co., the tin smelters, of Hayle, Cornwall, were contemplating an extension of their business by erecting a new smelter for foreign ores at Liverpool. As it is commonly supposed that the metallurgy of the non-ferrous metals is a stagnating if not decadent industry in Great Britain, this news was of exceptional interest. Since writing the paragraph in question, it has occurred to me that I ought to mention the fact that one of the old Swansea firms has recently been re-organized and extended on modern and up-to-date lines. This includes the business of Williams, Foster & Co., and Pascoe Grenfell & Sons, Ltd., of the Morfa, Middle Bank, and Upper Bank Works, Landore. This is an unworldly name, it is true, but it is already being paid for by large sums being put in by English metallurgical industries, and it would be doubtful policy to eliminate the old names. Williams, Foster & Co., of Morfa, have been copper smelters for generations, and Pascoe, Grenfell & Sons have been zinc and copper smelters at Middle Bank and Upper Bank for quite as long a time. The two firms were amalgamated in 1892 when Henry R. Morton & Co., of London, and the Metallurgische Gesellschaft, acquired the controlling interest from the trustees of the old owners. During the last two years large sums have been spent in re-modeling the plant. The new zinc distilling house at Upper Bank, and the new copper-rolling mills at Morfa have been admirably designed on modern principles. The zinc smelting industry at Swansea is flourishing, and ores are easily obtained from all parts. In fact, the smelters are somewhat independent in their manner of dealing with ore producers, and some of the English zinc mines can get better prices for their ores from Belgian and German smelters than they can in Swansea. As regards the smelting of copper ores at Swansea, this is without doubt a decaying branch of trade. It is difficult to get supplies of ores on a large scale. Matte and Bessemer bars are more readily obtainable, but even so the customs smelters, such as Vivians and Williams, Foster & Co., cannot meet the demand of their rolling mills by the output of their refineries, and have to buy refined bars to make up the short age. The firm of Williams, Foster & Co. and Pascoe Grenfell & Sons, Ltd., has spent something like £100,000 during the last year or two in making these improvements in the works.

I should like to give a pen picture of the Landore, Llanasmet, and Morriston valleys, behind Swansea. In spite of the Alkali Works Act, which prohibits the discharge of acid fume into the atmosphere, the districts on the two sides of the Tawe river are still the last places in the world. Smelting works, acid works, fertilizer factories, and smelter works, and a host of other works, vie with one another in rendering the atmosphere unbreathable. On a moist day when the mists hang over the valley the conditions are the worst. When you cross the Tawe on the ferry punt, which is fastened to a chain for protection against the force of the tidal current, you are reminded of Charon's journey over the Styx. The ferry takes you from the Morfa to the Upper Bank works. Vivian's acid plant is perched on a slag pile to one side, and behind rises the Kilvey hill, quite devoid of vegetation. As a contrast to this scene of desolation, the country to the west and south of Swansea is beautiful in the extreme, and the workers in Landore who, on leaving the scenes of their toils, proceed to their domestic circles at Sketty, Mumbles, and Langland Bay, are well compensated for the dreariness of their surroundings during the day.

A few months ago I referred in this column to the difficulties met by the San Francisco del Oro Mines, Ltd., which works the mines of that name near Parral, Chihuahua. The directors have been experimenting on a system of dry concentration, but have now given it up, and are turning their attention to improving their water-supply with a view of adopting wet concentration. The mine contains zinc and copper sulphides, but the lead sulphides are easy to separate by hand on the established lines for this class of ore. Hitherto the directors have been content to make ends meet by picking out the best quality of ore that could be sold direct to the smelters. In order to put up a new plant additional funds will be required. These are to be raised by re-constructing the Company on the basis of an assessment of $5, or 250,000 shares of $1 each. If everybody pays up, $35,000 will be raised in this way, but I very much doubt whether all the shareholders will be found ready to provide their quota.

One of the more recent ventures of the Australian group, identified in England with Bewick, Moreing & Co., is the Great Fitzroy gold and copper property at Mount Chalmers, near Rockhampton, Queensland. The Company was formed in Melbourne more than a year ago, 232,000 in shares being paid up, the balance being paid in 2 years. The property is situated in a district admirably provided as working capital. The ore was estimated to contain 3 to 5% copper, and from 4 to 8 dwt. of gold per ton. A smelting plant on a semi-experimental scale was erected, and operations were conducted for some time with the object of ascertaining the right method of treatment, and during this time development was actively continued. The smelting plant and the mine are now reported to be in excellent condition, and the directors are going ahead with the extension of the smelting plant. During August 3303 tons of ore were smelted direct, producing 353 tons of...
mining, which contained 101 tons of copper and 618 oz. of gold. When the new plant is completed, the capacity will be increased to 9000 tons per month. It is expected that the payable ore Government will later to be treated at the smelter. The ore treated on June 30 amounted to 334,900 tons above the 225-ft. level. The main orebody at this level is about 100 ft. wide, and is proved for a length of 300 ft. Development work has been commenced at the 300-ft. level. In addition there is a southern extension of the lode, high in copper and gold, and of considerable extent. It is, however, silicious, and the ore will have to be extracted to a branch line of railway to the mine, by which means the cost of treatment will be substantially reduced. The Company has sufficient funds in hand to pay for the extension of the smelter, so that no new issue of shares is to be made.

A dredging proposition that has been recently put before the public in London is the Queen Gold Dredging Co., which has acquired gold gravels in Tierra del Fuego from local owners. I believe this is the first dredging property in that district that has been introduced to English capital, though many dredges are in operation, worked by Argentine or Chilean owners. The engineer who has been instrumental in interesting London promoters in this subject is Percy B. Weston. He has now proceeded to the spot as manager for the Company. The dredge has been designed by Cullin Brothers, and is on its way out. The deposits are covered with a peat overburden, which will be stripped by means of a grab excavator. It will be interesting to follow the fortunes of the Company.

The report of the Mexican mines of El Oro, Ltd., for the year ended June 30 last, is interesting reading. This Company is an off-shoot of the El Oro Co., and was floated by the Exploration Company just four years ago. The property lies to the north of the Esperanza mine, and contains a continuation of the same vein which passes through the Esperanza and the El Oro ground. The Company was floated with a capital of £180,000, of which £71,749 was subscribed in cash. At first considerable profits were made by the sale of high-grade ore to the smelters, and additional funds were thus available for the completion of the milling outfit. About £80,000 has been obtained in this way. The mill was completed last September, and commenced running on October 1. It consists of a 40-stamp mill, tube-mills, and cyanide plant. During the nine months up to June 30, 1908, the amount of ore treated was 62,394 tons, from which bullion to the value of £104,926 was recovered, being an extraction of nearly 13 dwt. per ton. In addition, 5000 tons of high-grade ore were shipped to the smelters, which yielded a net profit of £71,616. The realized profit for the year ended June 30 was £132,897, out of which a dividend of £45,000 has been paid, while £71,900 has been written off for preliminary development and cost of plant and buildings. The mine continues to open up well, and the reserves on June 30 last amounted to over 200,000 tons of ore running 11 1/2 dwt. gold and 6 to 7 oz. silver per ton.

**ROSSLAND, BRITISH COLUMBIA.**

**Report of Consolidated Mining & Smelting Co.—Concentration Problems at Rossland.—Output of Le Roi Mines.—Boundary Ore-Shipsments.**

The annual report of the Consolidated Mining & Smelting Co. of Canada, Ltd., operating copper mines at Rossland and Phoenix, the principal lead-silver mine of Canada, at Moyle, and an up-to-date copper-lead smelter and refinery, at Trail, B. C., is at hand. The Company paid its dividends $65,940 during the past fiscal year. The balance on hand, after an expenditure of $500,000 for development and after writing off $132,000 for depreciation of plant and equipment, and $27,000 on stores and doubtful accounts, is $33,500. Had the metal market not weakened, the profits of the Trail smelter would have been over $400,000 more than they were, upon the ore on hand at that time. The output of the smelter was increased 43% during the year, being valued at $6,425,501, against $3,785,146 for the previous year. The report shows that the value of the ore extracted from the War Eagle, Centre Star, Iron Mark, Snowshoe, Richmond Enrique, and St. Eugene since 1894 is estimated at $31,000,000. There are 19 miles of underground work in the Centre Star-War Eagle group, at Rossland, and 12 miles in the St. Eugene. The Consolidated company is capitalized at $4,698,800, in 100 shares. Local authorities consider that the Consolidated company has made a good showing, when everything is taken into account. The big concentration at Trail for the reduction of Rossland ore, and which was acquired by the Consolidated company in the re-organization, is being dismantled. The old capitalization of the Rossland Power Co. was $500,000, but when its assets were taken over by the Consolidated, the watered stock was drained off, and these assets taken into the new Company at $60,000. It is now a recognized fact that the former management of the Centre Star-War Eagle mines made a mistake in building this concentrator eight miles from the mines. The freight rates, lack of sufficient water, loss in the tailing, and general re-enactment of the Roesland ore led to the abandonment of the plan to concentrate Rossland ore at Trail, it being found more economical to send the ore direct to the smelter. The valuable machinery that was distributed throughout the huge building has been sold or shipped by the Consolidated to its various properties, where it was needed. The Rossland Power Co. had a heavy item on the debit side of the ledger because of this enterprise, and there is little doubt that the Consolidated company will stand quite a loss, even though it took over the assets of the power company on a close margin.

The concentration of Rossland pyritic ore has so far remained an unsolved problem. There is an abundance of gold ore on the dumps and in the Rossland mines that assays from $3 to $5 in gold. The Le Roi Mining Co. employed an expert on milling and erected an experimental concentrator, only to find that it would not pay. The White Bear Mining Co. erected a costly mill and operated it at a small profit, crushing the ore by means of stamps and catching a major portion of the concentrate on Wilfley tables. The Le Roi No. 2, Ltd., is operating the concentrator and making a profit on the low-grade ore. The ore is first crushed in Blake crushers, whence it goes to the Chilean mills, and then the heads run over two Wilfley tables for coarse concentration and to two others for saving the finer concentrate. The oil-concentrating plant is not in operation, having proved uneconomical. The manager's report on the operation of the Le Roi No. 2, Ltd., for Au-
gust states that 2420 tons of ore was shipped. The net smelter-receipts were $47,139 for 2106 tons of ore, and $550 for 69 tons of concentrate.

The report of A. G. Larson, superintendent of the Le Rol, for the month of August states that 6191 tons of ore was sent to the Northport smelter. This carried 2237 oz. gold, 336 oz. silver, and 117,000 lb. copper. The sum of $900 was depited on development during the month. The estimated value of the output is $77,700, and the profit $15,000. Most of the ore now found in the lower levels assays from $9 to $11, but some richer ore is being opened up, and occasionally ore is found that contains $35 to $40 gold per ton.

Ore shipments from the Boundary mines for the week ending October 3 again show a slight decrease. The total being shipped is 34,050 tons, which is a decline as soon as the Loor, cam Oro Denoro shipping. The ore shipments from the Phoenix mines have now passed the one million ton mark within the calendar year. The Granby contributed 76%, the B. C. Copper 21, and the Dominion Copper Co., Snowshoe, Sally, and Crescent the remainder. The Boundary mines, more particularly the Granby and B. C. Copper, have shipped more heavily this year than heretofore. The Boundary mines have been forced to make heavy shipments by the existing low price of copper and the high cost of production. The disastrous fire at Fernie was the cause of a coke shortage which affected the Granby and Dominion Copper companies to a considerable extent. This, however, did not affect the B. C. Copper Co. directly, as it obtains fuel from a point to the Crows Nest district which was not damaged by the fire. Then came a shortage of cars, which caused the output to be lower for the week ending October 3. This car shortage was the result of the heavy wheat shipments to the East.

While mining operations are being continued on the Stemwinder and Rawhide mines of the Dominion Copper Co., and a large quantity of ore is broken and ready for shipment, work has not resumed at the Boundary Falls smelter. It is rumored that the company is once more short of funds, and that the local officers are awaiting advice from the Eastern office before resuming at the smelter. The Dominion Copper Co. is in a fair way at present to make a profit. The Granby and the B. C. Copper Co. have demonstrated in a satisfactory manner that the mining and smelting of the low-grade copper-gold ores of the Boundary can be made to pay a good profit. With an advance in the market price of copper to 15 or 15c. the Dominion Copper Co. could be placed on a sound basis with little capital.

**BUTTE, MONTANA.**

**Amalgamated Extends Holdings at Great Falls.** — Electricity for St. Paul R. R. on Rocky Mountain Section.—Davis-Daly Re-organization.—Butte Copper Montana Co.—Butte Extension.—Opening of Panhandle Smelter at Pondary.—Butte & Arizona Mining Company.

John D. Ryan, managing director of the Amalgamated Copper Co., and presumed to represent H. H. Rogers, the Rockefeller, and others, has purchased 3500 acres of land between Great Falls and the falls of the Missouri river, where that company acquired nearly all of the water and power rights some time ago. This purchase gives the Ryan group of capitalists complete ownership of the river-front and of tremendous power resources. They will build two huge power stations on the river and will furnish electric power for a large portion of the industries and mines of Montana. Two power lines will be built to Butte, and electric power will be furnished to all the Amalgamated and other mines. Contracts have already been made for furnishing electric power to the Chicago, Milwaukee & St. Paul railroad, which will operate its trains over the Rocky mountain country, and to the mines, as the power can be furnished and the road electrified. Electricity will be used by the St. Paul system over a large part of western Montana and through Idaho. The power company owned by Mr. Ryan and his associates is one of the most important in the West. They are investing several million dollars in it.

The Boston & Corbin Copper Co., operating in the Corbin district, has secured estimates and plans for a new surface plant. It has been decided to install a first motion hoist with a capacity for sinking to a depth of 2000 ft. The lowest workings are now at a depth of about 700 ft., and the veins on which driving is now in progress are good. The company is making preparations for opening the property on broader plans, and to raise through the ore bodies from the 1200-ft. level, when that is opened.

Notwithstanding the statement from the re-organizers of the Davis-Daly Copper Co. that fully 99% of the old stockholders had exchanged their stock and paid the first installment of the assessment of $2 per share, it is evident that a very large amount of the stock is deliquent. It is stated that the new company has interested London capital in the enterprise, the Venture Co. being mentioned in that connection. The Davis-Daly Co. owns about 200 acres of ground in the Butte copper district. The oft-repeated statement that the company owns 400 acres takes account of several mining claims west of Butte and outside of the copper belt, and also of a ranch of about 200 acres situated south of Butte. The mining claims in the district are so situated that it would seem impossible to develop a big copper mine, so far no ore has been found. Sinking is still going on in the Colorado shaft, where the only work of the Company is being carried on. The shaft is down nearly 1400 ft. It is being sunk at the rate of about 100 ft. per month. 'The Colorado has opened several veins carrying bunches of ore, but not of a commercial character. The ore is heavy io zinc, and until a process is discovered for the successful treatment and separation of the copper from the zinc, there is but little prospect of getting much of a great quantity of useless ore. The same character of ore predominates in many mines, in the Butte district, which have never been able to pay. These include the old Emma, the Lexington of the La France Co., the Blackrock of the Butte & Superior Co., and the Alice of the Butte Coalition Co. A former official of the Davis-Daly Co. says it will require $400,000 more to thoroughly develop and equip the Colorado mine. The re-organization and re-financing of the company is intended to put $1,200,000 in the treasury, and half of that will be paid out at once in taking up options and paying attachments and pressing debts, leaving $600,000 with which to carry on development. If $400,000 will be required on the Colorado alone, it would appear that the plans of the re-organizers do not take a very distant future into consideration, or they are based on the hope that a big producing mine may be made out of a small one.

A number of inquiries have been received in Butte recently relative to the affairs of the Butte Copper Montana Co. and the Butte Copper Co. The two companies were organized on the same property, the former having been organized in New York and made a holding company for the other concern. The latter owns a two-thirds interest in股票 Robert Emmett No. 1 and Robert Emmett No. 2, one-third in the Anselmo No. 1, Anselmo No. 2 and Trifles. Private parties own the other interests in the Anselmos and Trifles, and the Butte Coalition Co. owns the one-third in the Emmett. The well-known policy of the Coalition people is to sell no mining property, and to permit no joint owners to operate it, so that the Butte Copper Co.'s ownership in the Emmett is of little value. The company is not in a condition to expend investments on property in Butte and Trifles, but allowed them to lapse. The promotion and management of the Butte Copper Co. have been subjected to much criticism. The promoters and officers of the company represented that the company owned all interests in the Trifles and Anselmo mines, and had an abundance of money to carry on development for several years. On this representation stock was sold in Butte, but as soon as Butte was 'milked dry' the officers of the company went to New York and organized the Butte Copper Montana Co., the so-called 'holding' company. When news of this action
reached Butte the stock of the Company on the local exchange dropped from $1.15 per share to nothing. A few days ago a lot of stock was offered at 5c. per share and found no buyers. E. H. Sherman, of Butte and Chicago, principal promoter of the two companies, has been forced into bankruptcy. John Macfie, former mayor of Butte and a former lieutenant of F. Augustus Heinz, is interested in the Company. It has no indebtedness, and it is likely that with an improvement in financial conditions throughout the country, another effort will be made to finance it.

The Butte & Montana smelter at Great Falls is now receiving all of the ore mined by that Company. During the long shut-down many improvements were made, aiming at greater economies in the handling of ore. Work is progressing on the new smokestack, which will be the highest in the world. When completed it will enable the Company to make a saving in the flue-dust at a profit of $150,000 per annum. The cost of the stack will be about $350,000, so that the saving will pay for the expenditure in less than two years. Work on other changes and improvements at the smelter are still going on.

The Panhandle smelter at Ponderay, Idaho, which has been purchased by interests representing the independent mine operators in Montana, Idaho, and Washington, will be 'blown in' October 20. The smelter has been improved and repaired and is now in shape to handle all the ore that the Panhandle interests produce. The ore is already on the ground, and contracts have been made for enough more to keep the smelter running continuously. Its success is so far assured that plans are being made for an enlargement of the smelter. The opening of the anti-trust plant is to be made an event, and excursions are to be run to Ponderay from places in Montana, Idaho, and Washington.

Miners from the mine of the Butte & Arizona Mining Co. indicate that the adit is approaching the orebodies, as a large quantity of water has been struck. The adit, which is now about 3000 ft. long, is being driven by contract. In August the adit was extended 107 ft. The contractor is Casper Schultz, of Butte, who was superintendent for the Company last year. The face of the adit is about 900 ft. under the surface of the outcrop. All the damage done by the fire last spring has been repaired and new buildings erected. The property is situated about 35 miles from Butte, near the Mexican boundary, the Cananea mines being in plain view. A number of seams of ore were cut by the adit, and some driving was done in the search for ore. The management of the Company has great faith in the property.

The Butte & Arizona coal mine operators and the miners have reached an agreement and the general strike of miners in this state has been averted. The old agreement was renewed, and there will be no change in the wage schedule during the next two years.

SALT LAKE, UTAH.
Utah Copper Co.'s. Output.—Transportation Difficulties. — Effect of Closing Tintic Smelter.—Development West of Oquirrh Range.—Majestic Mines.—Utah Apex Mining Company.

Although the concentrating mills at Garfield were somewhat handicapped for ore, owing to deficient transportation facilities, the Utah Copper Co. made a good output in September. The concentrates produced for the month, amounting to 4,500 tons, yielded a net profit of $225,000. The Boston Consolidated undertook to start four more units of its mill, making eight in all, but the management was unable to take care of the anticipated tonnage. President Charles M. MacNeill and other officials of the Utah Copper Co. were in Utah last week. During their stay the important subject of ore transportation in the Bingham district was again discussed. Mr. MacNeill is said to have expressed disgust with the service the Company is receiving from the Gould system of railroads and to favor the building of the extension of the Bingham & Garfield railroad without unnecessary delay. The rights of way have already been secured, and 16 miles more track would make the Utah Copper Co. absolutely independent, as far as concerns the transportation.

The temporary shutting down of the Tintic smelter has had the effect of greatly reducing the output of ore from the Tintic district, and one company has suspended dividend payments until normal conditions prevail. This is the Colorado Mining Co., which has been one of the principal shippers of ore to that plant. It has been the policy of the management of this Company to share profits with stockholders whenever the treasury contained a surplus.

Two other Tintic companies, however, have announced dividends for the third month, one company paying $25,000, and the Sioux Consolidated, $30,000, the latter making its initial appearance in the dividend column.

Attention is again being directed toward the development of that region lying west of the Oquirrh range of mountains, directly opposite Bingham. Bingham people are interested in the Bingham Metal Mining Co., which has been pushing a vigorous campaign of development for the greater part of the past two years. An adit has been driven 1400 ft., which is expected to eventually tap the ores at a depth of about 1200 ft. vertically from the surface. This Company is said to have expended nearly $75,000 for development purposes. Isaac Meserve, of Boston, is at the head of the enterprise. The Great Divide Mining Co. owns adjacent mining property, and is installing a compressor and power-drills at present, with the view of increasing activity. No mines of any consequence have been developed as yet on the west slope of the mountains.

J. M. Dick, vice-president of the Majestic Mines Co., inspected the properties of that Corporation in Beaver county last week, and made the statement that development would again be undertaken upon an elaborate scale; and that the financial end of the enterprise had been straightened out. J. H. M. Moffat, of Butte, has been appointed A. D. Sherman, his successor, was also announced. Mr. Moffat was formerly superintendent of the properties of the Newhouse Mines & Smelters corporation.

When President R. R. Hastings and Treasurer J. W. Horne, of the Utah Apex Mining Co., departed for Boston on October 4, they were satisfied that the Bingham mine had at last reached a paying basis. Never before have physical conditions at the Utah Apex been so satisfactory as at the present time, and the officials frankly expressed their appreciation of the results accomplished during the administration of Robert S. Oliver, the present manager. Mr. Oliver recommended a new plan of operation. It met with the hearty approval of the officials, and will mean a saving to the Company of about $50,000 per month on the taxes of extraction. The plan involves making connection between the Parvenue and the Parvenue mine under ground by means of a three-compartment raise, giving room for the operation of two cages, besides a manway. The raise will be 5700 ft. high. The ore will require no handling after being loaded into the mine cars, which will be dropped to the Parvenue adit, thence conveyed to the new ore-bins shortly to be constructed at a convenient point on the Boston Consolidated branch of the Denver & Rio Grande railroad. The point selected for the mill is approximately 2000 ft. from the portal of the Parvenue adit, while the distance from the latter to the Boston Con. switch is nearly 1500 ft. From the ore-bins the first-class ore is loaded automatically into railroad cars. This ore has a gross value of $30 per ton, on the basis of present metal prices, and nets the Company $25. The second-class ore will have to be delivered to the mill later. The question of the best way of providing mill facilities is still undecided. On the fourth level of the mine has been developed what is probably one of the largest bodies of galena ore ever found in the Bingham camp. It has been explored for a length of 530 ft. The width of the high-grade streak averages 4 ft., and the mill-ore from 10 to 15 ft. There are three well-defined ledging-planes in the property, all between line, which are designated respectively as the Andy, Parvenue, and Parvenue. Connecting the Parvenue adit with the upper workings will eliminate the aerial tramway, and will introduce large economies at the Utah Apex mine.
MEXICO.
Revision of Railroad Rates.—Oaxaca Iron and Coal Co. — Re-organization of Smelting Companies in Oaxaca. — Navidad Mine Increasing Plant.—Activity in Ejutla District.

As yet the railroad commission has given no decision on the proposed increase in freight rates on imported coal and coke, but at a meeting held by that body on the afternoon of September 29, in Mexico City, the leading representatives of both sides of the controversy were heard at length. The coal producers claimed that they could furnish as good an article as was imported, and need at least three-fourths of the country's demands, but in order to do so they must have some kind of protection against foreign importations; the railroads claimed that, to meet the costs, the rates must be raised, and that it was reasonable to ask $1 more on coke than on coal. The mining men stated that the rates on the Mexican railroads for coal and coke were already higher than in the United States; that they could not get delivery from domestic producers; that the domestic fuels, though considerably improved in the last

two years, were still of an inferior grade, and for a number of reasons they were forced to use a considerable quantity of foreign coal and coke, and any increase in the rates on the same meant increased costs in smelting operations, and a consequent necessity of raising the charges for smelting. The mining men reiterated the statements of the smelter men, dwelling particularly on the possibility of increased smelting charges, and stated that with the metal markets as they are, the burden on the metal mines was already more than they could continue to bear. They begged that, if the rate must be increased in order to protect the home producer, all possible consideration be given to the metal mines in fixing a moderate tariff. Both sides asked for a prompt decision either way, as being preferable to suspense. The Chamber of Mines was most active in the discussion, and it is preparing for strong action on the anti-foreign article in the proposed new mining law.

The Governor's message to the State legislature of Oaxaca at its opening session on September 16 stated that the holders of the concessions for the Oaxaca Smelting & Refining Co. and of the Magdalena Smelting Co., had both asked for extensions in which to re-organize, and that he had hopes that both might resume operations before the end of this year. He further stated that the Oaxaca Iron & Coal Co., of Tlaxiaco, had developed a good marketable coal, and that its work was rapidly showing the value and proving the extent of the Oaxaca coal fields. The Oaxaca

Iron & Coal Co. has taken up more than 1100 pertenencias of iron and coal lands, and with the diamond-drill is thoroughly exploring the ground, having proved up several veins of a good quality of coal from 2 to 10 ft. thick. This Company expects to enter the market during the coming year. The Navidad mine, in the Sierra Juarez district of Oaxaca, continues in bonanza, and as a consequence is adding 20 stamps and a tube-mill to its equipment, thus increasing the capacity of the mill from 60 to 150 tons. The treatment has been made considerably more efficient by the addition of the Pachuca cyanide tank. The San José de Gracia, also in the Sierra Juarez district, expects to have its cyanide plant in operation before the end of October. The Providencia-San Carlos Mining Co. has made its last payment on the San Carlos property, and it is believed that operations will be resumed there within the next month. The mill of the Rosario Mining Co., of Oaxaca, is to be moved to Cuatro Amígos, on the Manzanito river, for power purposes, and the capacity of the mill is to be doubled. Joseph Kimball and associates, of Salt Lake City, have been visiting Los Ocoites mine, in the Ejutla district, in-
Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Complete change of clothing on entering and leaving mines is compulsory in Western Australia. The 'change-houses' are also required to be kept exceedingly clean, and the regulations also compel observance of strict sanitary measures below ground.

An acid-resisting cement may be made by the following formula: silicate of soda, 6 parts; glycerine, 1; red lead, 3½; fine cinders, 10 parts. Mix the silicate of soda and glycerine first and then add the red lead and cinders. The cement sets soon after mixing, and unites with brick or portland cement to form a strong joint.

Pressure does not necessarily increase the solvent effect of solutions. The general law governing the relations of pressure to solvency is that the change must lead to a reduction of volume. Consequently, if the solid substance and the solvent contrast when solution occurs the solubility will be increased with increase of pressure, and vice versa. The silicates generally dissolve more readily with higher pressure.

The Chocó is the name of an 'intendencia' in the western part of Colombia, but the historic use of the name is in connection with the famous placers which paid the 'king's fifth' on a recorded production of over $200,000,000 gold. The placers are also unusually rich in platinum. The early production was from the shallow streams and 'high banks' along the Chocó river. The region is one of the most promising in South America for dredging enterprises.

Carbon dioxide, or carbonic acid gas as it is commonly called, has been used to some extent in fighting mine fires, but its employment is attended with some peril. Carbon dioxide in contact with the burning mine timbers, after the available supply of free oxygen has been consumed, will be reduced to carbon monoxide (CO₂ + C → 2CO), which is liable to produce disastrous explosions as soon as dilution with fresh air takes place. Present practice favors the use of sulphur dioxide to extinguish mine fires. It is not only safe and efficient, but is also far less costly to produce than CO₂.

Aneroid barometers possess individual peculiarities which must be known for each instrument in order to employ them with safety. Without such knowledge, even the indicated difference of altitude between two near-by points, which may be reached before temperature and moisture-conditions in the atmosphere can have changed, is not to be trusted. Each instrument is generally reliable within certain limits of altitude, one being safe at low levels, another at moderate elevations, and so on. No aneroid barometer should be used for serious reconnaissance leveling until it has been thoroughly tested under partial vacuums corresponding to the atmospheric pressures at different elevations above sea-level. No aneroids possess a constant error throughout the range of pressures they are supposed to record. Furthermore, the errors once determined will not apply throughout the life of the instrument, this being due apparently to gradual relief of strain between the molecules in the corrugated metal plate. If an aneroid can be tested against mercurial barometers within the limits of altitude in which it is intended to work, it is better than to trust to the air-pump.

Roll crushing has an advantage over other methods in that it produces a more uniform product, that is, less pulverulent material which will pass a 200-mesh screen will be produced. For highest economy and efficiency the rolls should be set to crush the average maximum size of ore-particle fed to one-third its original diameter. Further reduction of volume at one crushing leads to excessive wear and tear on the machine, and is less economical in the end than division of the duty. Over-work in roll-crushing leads to high costs, and loss of time in making repairs.

Petrographic province is the term applied to a group of rocks having a chemical relationship indicating a derivation from a common parent magma by normal differentiation. The volcanic rocks throughout certain zones present this evidence of consanguinity, and within such a zone similar phenomena of ore deposition are likely to recur frequently. The identification of the eruptives at any locality as pertaining to some petrographic province in which the economic geology has been revealed by mine workings, may lead to warrantable inferences concerning the probable conditions attending a new deposit.

Dynamite should never be stored in tunnels, nor in any place where dampness exists. Although a tunnel may seem dry, all rock-in-place contains from 3 to 8% of moisture, which is continually being brought to the wall-surface in underground workings by capillarity, where it is evaporated unless, for want of ventilation, the air is saturated. Thus the rock is continually contributing moisture, which is greedily absorbed by the sodium nitrate in the dynamite, that salt being highly hygroscopic. As soon as the sodium nitrate has deliquesced, that is, melted from absorption of moisture, the homogeneity of the dynamite becomes disturbed, and the 'dope' fails to retain the nitroglycerine, which then leaks out. The watery substance often seen on cartridge-paper, and the oily stain seen in dynamite boxes, is due to the leaking of the nitroglycerine. A cartridge in this condition is far more liable to accidental explosion than sound dynamite, and it is perilous and uneconomical in use. It will not develop the same energy as good dynamite; it is likely to burn and blow out instead of detonating properly; and it is a frequent cause of 'mis-fires,' and of the failure of a charge to explode to the bottom of a hole. Dynamite must be stored in a dry place.
Discussion.

Readers of the Mining and Scientific Press are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

Gold Dredges Large and Small.

The Editor:
Sir—I was much interested in the articles in the Mining and Scientific Press recently on the subject of small dredges. This interest was added to when I read a similar article in the editorial column of a contemporaneous journal. The rather sudden interest in this subject has made me curious as to the cause, and for the good reason that, as the representative for several years of a manufacturer who did some work in this particular line, it never struck me that the people who asked prices on small dredges were in the same class with the operators in California. It is easy for a manufacturer of any line of machinery to understand why a small dredge of the same relative class should cost more than a large one. But it is hard to show that to a man who is not familiar with manufacturing. My efforts to sell a small dredge that would do work as satisfactorily as the large ones used to meet with frequent rebuffs on this account. With all this experience I can but say that the small dredge-buyer has not kept pace with others in the same line. Witness, if you please, the rise in price of the dredges in the California field within the last ten years. Cost has not been the prime consideration, otherwise the success attained would have been impossible. The essential has been to make something that would do a certain kind of work at a reasonable price. This obtained, and we have something upon which to base what a reasonable price should be. But until we had gotten the successfully working dredge, there was no basis whatever for making any statement of costs. It has been demonstrated so many times and at so many places, that it would seem as though lack of knowledge of what has been done would be the exception among people in placer mining.

The large investment necessary in building a dredge makes it impossible for a manufacturer to build them for experimental purposes, and the experiment would not be of value for every situation. The dredges which are doing such good work in California and other localities have been developed by the combined efforts of the manufacturer and the operator, and I see no other way to bring the small dredge up to that standard. There is undoubted a field for them, but the people who go into it must understand from the first that there is small chance that they can either buy as good a dredge for the same relative cost, or operate it as cheaply per cubic yard of dirt handled. These points tend to put difficulties in the way of the desired development, but should not be discouraging. I have designed several small dredges, all of which are working to the apparent satisfaction of the owners. One in particular was designed on the same general lines, as far as the arrangement and quality of the machinery is concerned, as the California dredges, and is working where it was not possible to determine fully what the conditions of the ground were. With this knowledge, I cannot agree that there are no successful small dredges, and in conclusion I wish to say that if the man who really wants a good small dredge will make his wants known in the right quarter, and will bear in mind that good engineering and an arbitrary price do not always go together, and that no dredge ever started, ran without small troubles, and sometimes big ones, he will have little difficulty in having his wants filled.

Denver, September 23.

Carney Hartley.

The Editor:
Sir—Can any of your readers supply figures for estimating the amount of royalties paid on the different systems of filtering slime? It is only fair, in estimating the cost of treatment, to include this item in each case, although I have failed to find it in any estimates. If this expense is included in the total cost, it would seem better to segregate it. C. W. Merrill claims to cyanide the Homestake slime for 24 cents per ton. Does this include his royalty?

A. Del Mar.

Cyanide Costs.

The Editor:
Sir—The data submitted in the following tables show the precipitation-costs, including melting and acid-treatment of zinc shorts at the Pinguico mill, Guanajuato, Mexico, for the month of July, 1908. The table gives the data compared with similar results from the Liberty Bell mill and the Desert mill, the latter figures being taken from the Mining and Scientific Press of recent dates.

C. E. Rhodes.

Guanajuato, Mexico, September 26.
Continuous Slime-Filter.

The Editor—Referring to Mr. Schorr’s article in your issue of August 8, I note that he mentions Bertram Hunt’s sand-filter, and suggests that it might be well for Mr. Hunt, or others possessing data on the subject, to tell what they know about the method.

As filtering plays an important part in the economic reduction of ores by cyanidation, and as Mr. Hunt has adopted this principle of filtering in his continuous slime-filter, a few remarks based upon an observation and experience extending over nearly five years with this type of filter may prove of interest. In 1897 there were installed, under Mr. Hunt’s direction, three of these filter-bottoms at the Black Oak mine, Tuolumne county, California, while working the tailing from the mill by the cyanide process. One filter was used in an 18 ft. vat, and the other two in two 8-ft. vats. The filter in the 18-ft. vat was used for three seasons. During that time the filter was taken out twice for the purpose of cleaning. It is obvious that this type of filter cannot be used in cases where the vats are cleaned by sluicing instead of by shoveling. For this reason it was necessary to use a single thickness of burlap to protect the filter-bottom. On all the rest of the vats, using the ordinary filter-bottom, two thicknesses of canvas or burlap were used, and the false-bottoms were removed once a month to clean out the sand which had accumulated beneath them. Of the material handled at the plant, 90% would pass a 100-mesh screen, 70% would pass 150 mesh, and about 4% would pass 200 mesh. This class of material at best leaches rather slowly, but a comparison of the two types of filters showed that the sand-filter gave a clearer solution, and leached more freely than the canvas or burlap-covered bottoms.

These two vats were used chiefly for experimental or testing work, generally for leaching purposes, but also for clarifying the solutions from the vacuum-pan. All kinds of material were leached in these two bottoms—slime, sand, and concentrate. For the last two years I have used these filters exclusively for filtering solutions prior to passing to zinc-boxes. They were practically in daily use for one purpose or another for nearly five years. I examined them on several occasions and found that the material which had been worked on these filter-bottoms had not found its way to any extent down the V-spaces through the 10-mesh (coarse sand) filling, showing clearly that, where capable of application, the sand-filter outclasses in general efficiency, cheapness of construction and maintenance, any other style of filter-bottom, whether used for the leaching or merely as a clarifying medium. The method followed in the construction of these filter-bottoms at the Black Oak mine was as follows: upon the floor of the vat were first laid pieces of 2 by 2-in. scantling, planed, about 12 in. apart, and parallel to one another. These were notched at intervals on the underside to allow free circulation of the solution. Resting on these scantlings, triangular pieces (made by cutting 2 by 3-in. scantling diagonally) were placed. The edges of the bases were placed about ½ in. apart, the ends conforming to the circumference of the vat. In the V-shaped spaces was first laid sharp quartz passing a ¾-in. screen. Enough of this material was used to act as a retaining floor for the next layer of material, which was ½-in. clean quartz. This was used to fill the V-spaces to about an inch from the top. Sufficient coarse sand (10 mesh) was then put in to level off. It would be natural to suppose that the sand and slime would eventually work down to the apex of the V-spaces, but it does not seem to do so to any appreciable extent. As soon as the filter has bedded itself, there will be no trouble with muddy solution. I have frequently used this type of filter in laboratory work, where I have found it equally efficient.

San Francisco, August 20.

E. N. Walker.

Constant Errors in Sampling.

The Editor:—I have been an interested reader of the Mining and Scientific Press for nearly three years, but during that time have seen no article upon the handling, shipping, and sampling of ores, along the lines of an investigation which I have followed at intervals, for some ten years. The results of this investigation are the conclusions that, first, there is no system or method of sampling ore that gives a correct sample; second, that any sample will ‘favor the bulk of the ore’; and third, that the first sampling of an ore will usually show the lowest value, more especially on an ore in which the coarse material forms the bulk, and is of the lowest grade.

These rules might fail where an ore is entirely made up of galena, with a certain value in silver, and possibly some others, but on such ore as Cripple Creek and the greater part of Nevada produces, they will apply. Of course it has no effect on mining companies milling their own ore, but how about the mines that keep up sampling works and smelters? In every instance, with gold and silver ores (excepting galena) the bulk of the material is worthless. For example, take one ton of ore having a value of $100 in gold alone. We have approximately five ounces of precious metal scattered through 32,000 ounces of waste—rather a large proportion in favor of the poor material! Is it possible to sample this ore correctly? If this is the case the shipper is always the loser, and it may explain a portion of the graft in connection with sampling works and smelters which are generally supposed to make more on an ore than their charge per ton for treatment, and it seems impossible for certain ore-buyers to explain their immensely profits.

The first experience I had along this line was in a ‘high-grade’ assay office in the Cripple Creek district, and was similar to this example: Take 9 lb. of ore assaying 100 oz. gold, figured as $1 per lb.; value of this lot $9; then take 1 lb. of ore at 1100 oz., or $11 per lb.; put them together and we have a total weight of ten pounds and a value of $20, or $2 per lb. No amount of mixing, nor any method of sampling will give a resulting assay of 200 oz. or $2 per lb. It will fall below.
The next case was on a dump-lease in the same district. The dump was screen and washed, and an automatic cut-out was arranged for the sample of screenings, and the slime was sampled with a paddle. Experience in this line of work had given us the net dry weight per bucket of slime and screenings, and later shipments proved our sampling to be reasonably close. In the first 10-ton carload was approximately 1/2 ton slime assaying about $120 per ton; 1/2 ton slime assaying about $60 per ton; some screenings running $40 per ton; and the rest, in screenings, assayed $33.80. This was shipped direct to the smelter and was settled for at exactly $33.80, which was the lowest value of anything that had gone into the shipment. A number of cars shipped later, through the sampling works, brought returns of from $2 to $5 per ton more than the average of our assays, one car being re-sampled a number of times, and finally umpired and settled for on the last and highest assay.

The next case was at a Gunnison county, Colorado, mine, where I was assaying rich sort ore. All ore assaying from $25 to $2000 per ton was thrown in and shipped together, giving assays of from 8 to 12 oz. gold, and, being a petzite ore, it also carried considerable silver. I spoke of the profit in grading ore, but no attention was paid to it until a new superintendent was put in charge, who said the same thing, so they concluded to save out a shipment of better grade. While assorting 1/2 narrow-gauge carloads of ordinary ore, about five tons of better grade was saved that brought $2500, and the rest ran over 9 oz. gold per ton. So the management was forced to admit that the taking out of the better grade had not reduced the value of the balance $1 per ton, so far as they could judge.

At Goldfield, Nevada, in the winter of 1905-06, I looked after the sampling of a 1000-ton shipment made from one of the large mines to a local mill. The ore was settled for on the sample taken at the mine, the milling company having a representative on the work. The 'values favored the fines' most decidedly, which were in small proportion to the coarse rock. All was put through a crusher and shoveled back into the ore-house, and from there shoveled into wheelbarrows and dumped into wagons. As the shovellers loaded the wheelbarrows, every seventh to tenth shovelful was reserved for the sample. The first method was by coning, but as everyone knew the 'fines' were the best, this method proved unsatisfactory, so two samplers were made of heavy sheet-iron, set on edge, in the form of a cross, with a slope from the centre outward. On the centre was fastened a funnel, such as is used in filling sacks, but with a short pipe, 8 in. diam., making 4-in. quarters, which allowed the ore to drop quickly and freely. Into this was dropped, not poured, the shovelful for the sample, alternate shovelfuls from opposite sides, the flaring top of the funnel gathering the ore into an even heap as it descended on the cross. This makes a good sampler. About the time this contract was completed, the company secured a lease on another mill which was of small capacity, so some ore was sent outside, 15 carloads of which were shipped to a sampling works at Salt Lake, after being sampled in the usual way at the mine, but in 12 out of the 15 cars, or 80%, the ore ran higher at the sampling works than at the mine, the greatest difference being over $900 on one car. If we figure 25 tons per car, the difference in value was $36 or more per ton on ore that assayed nearly $100.

The question arises, what did the milling company make on the 1000 tons that were settled for on the sample taken at the mine? This would go to show that the first sample was considerably the lowest in value, so if the sampling works had the first sampling they could turn the ore over to the smelter at a big profit, over and above their charge per ton, and might still do so on the second sampling.

Some time ago there appeared in the Mining and Scientific Press several articles by T. A. Rickard on Goldfield, Nevada. One installment began by saying that "Goldfield has squandered its gold." Various reasons were given, but no reference was made to the loss occasioned by the reckless methods of handling and shipping ore, which I will venture to say was greater than that charged against 'high-grading.'

In the Mining and Scientific Press of September 5, 1908, there appeared an article by S. E. Bretheron, on 'An Automatic Ore-Sampler.' I could make a number of comments on this, but will make but one. Toward the end of the article he says, 'Between the ore car and the chute from the crusher, pass the buckets of the sampler, so arranged as to time, size, and number, that an average of the coarse and fine is anywhere from one-twentieth to eight-twentieths, no matter how coarsely the ore is crushed." How is it possible to obtain an average sample of coarse and fine if the buckets are arranged as to time? It certainly takes longer for coarse material to pass through the cruiser than fine, so the result of any time arrangement gets more of the coarse than the fine, and if there is any difference in value the sample will get it. The only reasonably correct method is arranged according to proportion.

R. I. Green.

Fairview, Nevada, September 28.

The Editor:

Sir—This experiment was made at Patagonia, A. T., by the writer upon a silver-lead blast-furnace in normal operation. The furnace was 36 by 120 in., with a 6-in. bosh and a melting column of 15 ft., and was putting through 80 tons of charge daily, using a slag of 35% SiO₂, 27% CaO, and 28% FeO. The amount of jacket-water was 2000 gal. per hr., the water entering the jackets at 22°C. and leaving at 67°C., and therefore absorbing hourly 750,000 pound-calories. The coke used was 1000 lb. per hr., and allowing 7000 gal. per lb. gives a total of 7,000,000 calories. The jacket-water therefore absorbed 10.7% of the total heat. Besides the above, we have to consider radiation from the external surfaces of the jackets, the crucible, and the outer surfaces of the walls of the furnace.

Houghton, September 10.

L. S. Austin.
BEYOND THE MISSOURI.

BY BENJ. JOE WHEELER.

"I recently heard a man account for a case of stagnating pessimism by saying: "They don't get out beyond the Missouri river often enough." The man who made the remark was the President of the United States, a man who himself absorbed a good deal of his fine sense for the essential mood and manner of Americanism through his own sojourning in the upland ranges and ranches behind that self-same river. There was a time when Mason and Dixon's line made the frontier between the two constituent moods and interests of the land; nowadays it is the Missouri and the lower Mississippi that mark the boundary between the nation's halves.

I have always noticed when the train passes North Platte coming west, that men stop wiping their necks at the edge of the collar, and that they begin to ask each other for a match, without reference to present condition of bank account or previous condition of servitude. By the time we have passed Buffalo Bill's ranch, agriculture begins to yield to grazing, men sit on top of the horse instead of behind him, and the hard brims grow stiffer. And then you begin to search for the concept hidden in the phrase, "beyond the Missouri river," and concept there must be—or, otherwise, what is the use of holding a Trans-Mississippi or Trans-Missouri Congress? And concept there surely is, for who has ever shifted his life from one side of this frontier to the other without feeling he is in another world.

If you look into the maps in the physical geographies, you will see that almost all the land beyond the river is painted brown in deepening shades; for most of it is over two thousand feet above the level of the sea. The trans-Missourians are nearer the stars, though farther from the safe-deposit vaults.

In the trans-Missouri region too the air is thinner, but the skin is thicker. It has to be—a little. The sticks are thicker. And almost everybody carries one. It is part of the individualism of the region that almost everybody is it, or prefers to be regarded as it—at any rate, it will generally be found profitable to treat him as such. This quality of illness is, in other words, somewhat more generally distributed among the population than over yonder. Hearts beat several times a minute more here than over yonder, but then, there is more here for hearts to do than there. Here the blood flows freer; there, the perspiration. But blood is thicker than water. Here the air is dryer; there, the hearts are dryer.

Here to the west of the Missouri is the land of elbow-room. Everybody feels it, and acts it. Everybody likes to wear his arms akimbo, and put the space to some good use. Do you know that though we have here but one-fifth of the population, we have a good half of the area, and surely two-thirds of the breeze. We are a breezy people in a breezy world.

On the other side they positively jostle against each other, so thick are they set. Massachusetts has 540 to the square mile; New York, 150; California, but 9, and Wyoming but 1. When a man has a whole square mile to himself, if he does jostle, he is likely to have acquired momentum in getting there. And that is what we find in fact. Detached ears on a grade unite and come to a halt with less peaceful results than a well-coupled train. But it is glorious to be free and have room enough. The biggest men there are, the biggest-hearted and the most self-reliant, come from these breezy, free, square miles.

To the east of the Missouri they are wont to accept the rainfall as dispensed by Providence. They are like the Puritan settlers of New England, who voted to adopt the laws of God until they had time to make better. To the west of the Missouri they propose to put the water on the ground when and where they want it. It has an audacious ring, especially when there isn't any water in sight, but it is part and parcel of that whole endeavor of civilized and scieneced man whereby he twists Nature to his uses, and by prying on her secrets, with what he calls his science, learns to domesticate her to his yoke and rule her by means of her own habits. The use of irrigation represents one of the highest and most characteristic activities of civilized life, and those who are forced to practice and develop it receive thereby high education, both in the scientific control of Nature and in the sociology of co-operation.

But there is one thing which, more than dry air or dry farming, more than heart-beats or elbow-room, more than grazing flocks, or teeming mines of yellow ore, or orchards of golden fruit, helps to yield the ultimate concept of "beyond the Missouri," and that is the long haul. Perhaps this is only a corollary of our elbow-room, but certain it is that our entire social and economic existence is conditioned by the fact that most of what we get and what we send must be carried over great spaces. In railroads we live and move, and in transportation we have our being. Material substances, whether ore or fruit or meat, are in themselves of no value, but only as they are set down where there is need and use for them. Wealth is created, not by growing anything or digging anything out of the ground, but by classifying material substances, and transporting and assembling them according to human need for their use. The railroads are our great public instrument for accomplishing this end, and nowhere is railroad transportation so closely wrought into the very life-physiology of a community as here beyond the Missouri. It is a matter of life and death. It is not raincoat or ring, but tissue and blood. Their joint interests are not separable. The prosperity of the one is the prosperity of the other. A finer consciousness of this mutual interdependence and of a mutual responsibility would be advantageous to both.

But there is still one more item for our trans-Missouri concept. The early settlers of this continent occupied first a fringe of the Atlantic shore, and their faces were set toward Europe and the East. Then they pushed back into the interior, but they backed in; their faces were still set toward the Atlantic and the East. It was not until the prairie schooners had crossed the Missouri, that prongs and faces were set toward the West. And now that we
have found another ocean, and begin to see that our Nation has destiny and tasks in terms thereof—a destiny and tasks that will may make its future history to be as certainly controlled by its position on the Pacific facing Asia, as was its early history controlled by its position on the Atlantic facing Europe, portentous as these tokens are, it still remains that it is only the people of the prairie schooners and their successors who really set their faces toward the West.

So there is good reason for the Western people to assemble in convention. I am glad you are here and now living up to your right, and as incidental there to I should be glad to have you visit Berkeley, and see a university we are trying to develop in accordance with trans-Missouri needs, for trans-Missouri uses, and for the general good of trans-Missouri people.

**EUCALYPTUS FOR MINE TIMBERS.**

Written for the *Mining and Scientific Press* by A. H. Martin.

The growing scarcity of timber and the increasing cost attendant upon the demand, is causing concern to operators of mines throughout the country. Several of the cheaper and more common varieties of woods have been tested for mine timbering, and recent trials indicate that the common eucalyptus can be made to answer the purpose satisfactorily. The eucalyptus or 'blue gum,' is a native of Australia, but attains an excellent growth in the valleys of central California. The trees attain large dimensions in from ten to fifteen years, and at any time after the tenth year would be available for mine timbers. There are about 150 varieties of the eucalyptus, but only about ten of these are suitable for timbering or as substitutes for hardwoods. Large groves flourish in luxuriance in the Santa Clara valley, particularly near San Jose. The better varieties of eucalyptus are light, elastic, straight-grained woods. The trees can be grown in almost any soil, and after the third year require little care. They are exceptionally rapid growers and are said to be especially adapted to the desert regions of the West, provided that a small amount of water is available.

The railway companies have been quick to realize the value of the eucalyptus for commercial purposes, and both the Santa Fe and Southern Pacific have planted large groves. The Santa Fe railway has completed arrangements to send E. O. Faulkner, manager of its timber and tie department, to Australia, for the purpose of studying the various species of the eucalyptus. Mr. Faulkner will examine the trees with a view to obtaining the best varieties for planting in California, as the Santa Fe intends planting 500,000 during the coming year. Up to the present time the eucalyptus has been successfully raised only in California, but many timber experts believe that some of the hardier species could be grown in the Mississippi valley. The Southern States are adapted to the rapid growth of the trees, but California will always be the largest grower.

The timber problem is rapidly becoming a most important one to mining men throughout America, and if the eucalyptus can be made to answer all demands it will result in a large saving for mine operators. Some species are practically imperative to decay, and will outlast any pine or spruce now in general use. With proper preservatives the life of the timber would be materially increased. Throughout California, and in many parts of Arizona, Nevada, and Utah, it would be economy for mining companies to set out groves of trees as an adjunct to their mining operations. The yield per acre at each cutting would exceed 200,000 ft. board measure, and as a cutting can be made every 10 years, this averages 20,000 ft. per annum, which at $25 per thousand gives a gross value of $500 per acre per year. The cost of planting and cultivation will not exceed $320 for the 10-year period. The United States Government has been planting extensive areas to blue and sugar gum in the Tejunga canyon on the forest reserve near Los Angeles, and nurseries are being established to provide the young trees by the hundreds of thousands for setting out along the foothills of the Sierra Nevada, San Bernardino, and Santa Ana mountains. Irrigation is unnecessary if there is enough moisture in the soil to give the tree a good start and keep it going until the tap-root has penetrated deep enough to get away from the superficial influences of drought.

Secondary enrichment is exemplified in the Granite-Bimetallic lode in the mine of the same name at Philipsburg, Montana. The lode is a tabular body of silver ore from 1 to 20 ft. wide, which has been stopep for 4500 ft. along the strike and 2600 ft. in depth. The vein fills a fissure in monzonite, along which there has been but little movement. The primary ore has a gangue of quartz and rhodocrosite enclosing a large quantity of pyrite, arsenopyrite, tetrahedrite, and tennantite, with some galena and zinc-blende. Sparingly scattered through this ore are small specks of pyrrygite, realgar, and orpiment. This ore carries from 20 to 30 oz. silver and from $1.50 to $3.50. Above the low-grade sulphides, extending from 500 to 1000 ft. below the surface, is a zone of enriched oxide and sulphide ore in which the primary ore is cut by veinlets of ruby silver, argentite, native silver, and horn silver. This ore carries over 100 oz. silver and $8.50. Above the rich oxide and sulphide zone is a zone of leached oxides which extends to the surface. This ore carries less than 40 oz. silver and $2.50. An analysis of the mine-water from a long drainage adit shows that it contains 0.000147 SO₄, 0.000160 iron, with traces of silver and gold. These figures indicate that about 0.6 of a ton of iron and sulphate compounds are carried out of the mine every 24 hours. It is well known that ferric sulphate solutions will dissolve silver, and that these are precipitated again by the action of sulphides. Enrichment was favored by a relief which furnished an ample head; by fracturing of the vein subsequent to the deposition of the primary ore; and by abundance of sulphides in the primary ore.—W. H. Emmons.
THE ENGINEER AS A FINANCIER.

By John Hays Hammond.

On October 1 Mr. Hammond delivered his address as president before the American Institute of Mining Engineers. He said:

This is an era of expansion, and, conformably with the change in commercial conditions, the function of the mining engineer, as well as that of his confrères in many other professions, has also expanded. From his capacity of an engineer, limited to the determination of technical questions, the engineer of today has come to assume an economic importance in those branches of industry dependent upon engineering skill for their development.

He is indeed an engineer of limited usefulness who does not go further professionally than to submit a purely technical report on subjects presented for his consideration. While he has the same responsibility as formerly in the solution of the technical problems involved, he is further expected to supplement his report with advice on the financial and commercial aspects of these problems. For the great majority of problems presented to the engineer ultimately involve the determination of the pecuniary relations of the proposition under consideration.

The great corporation lawyer no longer earns his fee by merely submitting his opinion as to the legal issues involved in lawsuits affecting the corporation; he now assumes charge of the entire legal work, including both the organization of the corporation and the maintenance of its legal status thereafter. In like manner the engineer, whose report was, as I have said, formerly confined to the determination of the geological and other cognate features of a mining enterprise, is now expected, not only to embody information on these subjects in his report, but also to give his opinion whether the property offered for sale in pursuance of such an enterprise is worth the price asked for it.

Moreover, if he recommends the purchase of a property he incurs a certain moral responsibility for its efficient management, inasmuch as his professional reputation depends upon the realization of his predictions as to the outcome of the investment. For this reason the engineer passes from the role of an expert to that of a consulting engineer, bound to supervise both the technical and the business management of the property purchased by his clients.

With this additional responsibility and the consequent increase of professional opportunity comes an extension of the field covered by the ethics of the mining engineer. Our professional duty may be regarded from three points of view: First, the relation of our work to our employers; second, its relation to the investing public; and third, its relation to our individual interests.

The question has been often discussed among engineers whether it is professionally proper to make a report for the seller of a mining property. Such a practice has been sometimes condemned; but a little reflection will show that the condemnation is not warranted. For it is neither wrong nor unreasonable that the owner of a mineral property should desire to present such a statement of its nature and probable value as will secure the attention of possible purchasers; or that he should secure for such a purpose the assistance of one who knows how to make such a statement intelligently and in scientific language, i.e., the language which will convey a definite meaning to those who know it; or that he should pay such an assistant for his skill and labor. It goes without saying that no expert in such a case, or in any other case, may suppress or mis-state facts, or disguise or withhold his honest opinion in a statement to which he lends his name. Yet, this being a 'vendor's report,' is not advice to anybody to buy at a stated price, but only a description of the property (usually without any mention of the price at which it would be to the purchaser a profitable bargain). There is nothing dishonorable or unprofessional in honestly making, for the owner of the property, such a description. But there is often danger that it may be afterward used as if it were advice offered to a purchaser. In any such report, therefore, the fact that it was made for the owner or vendor, or his representatives, should be clearly stated beyond all misunderstanding, for the protection of both the author and the reader. This precaution being observed, I see no valid objection to the writing of such a report by a mining engineer.

Nevertheless, it is an undesirable kind of work, particularly for young mining engineers, whose reputation for integrity and judgment, not yet established by long practice, may be, justly or unjustly, placed in jeopardy by any such expression of their opinions, and may be destroyed, in public esteem, by the failure of any mining scheme with which their names may have been thus associated. In their own interest they should accept such engagements with caution, and protect themselves with vigilance against illegitimate or misleading use of their statements. In short, they take, in such cases, a risk which older engineers, backed by a reputation already established, could better afford to take. As between the two classes, the question is one, not so much of ethics as of practical wisdom; yet we may fairly say that the avoidance of folly is in no small degree an ethical matter. It is worthy of notice that the wise proverbs and warnings of the good old book often make no great distinction between 'fools' and 'siners.'

In this connection arises the question of the acceptance of contingent fees. It seems to me that an expert of established and unimpeachable reputation is perfectly justified in recommending the purchase of a property and accepting compensation from the promoters; provided, first, and without qualification, that full publicity be given to the nature of his connection with the enterprise; and, secondly, that his compensation be contingent, not upon the successful sale of the property, but upon the subsequent success of the undertaking. In other words, an expert who makes a favorable report upon a mining property, for which he is to receive payment in money if the property be sold on his report, must needs have an unparalleled reputation for integrity to endure that revelation of this situation which he cannot
without dishonor withhold. But one who frankly avows that he is to be paid in the stock of the projected company, and therefore, as an investor of time, skill, and labor, is on the same footing as the investors of money, occupies a much less vulnerable position. In either case, and in any case, there is no safety—and, I may almost add, no honor—outside of the frank and full publication of all such circumstances as might be afterward called in question, criticised, or condemned.

This is the expert's golden rule: 'Tell unto others, now, whatsoever you would not have them tell on you (with unjust misunderstanding and scandalous comment) hereafter.'

Another question involved in the relation of a mining engineer to his employer concerns the acceptance of commissions from the sellers of machinery, supplies, etc., the purchase of which he has made as agent, or recommended as adviser. In many instances of similar nature affecting other professions, this practice seems to be established and condoned, if not avowedly justified. It is ever defended by ingenious sophistry, somewhat as follows: The manufacturers of certain articles are bound by trade agreements not to sell them below a certain price, or, in the absence of such agreements, do not dare to 'cut' the price, for fear of thereby invoking savage reprisals from their competitors. But this minimum price includes the salary or commission paid to a regular selling agent. If, therefore, the agent of a customer makes a purchase direct, without the intervention of their sales agent, they are willing to pay him 'the regular commission,' though they are not willing to reduce by the same amount their bill to the employer. The argument is plausible from the manufacturer's standpoint, and indeed it is hard to judge him justly. For if, in a given case, in order to gain a customer, he undersells his competitors, he may be committing the heinous modern sin of giving a 'rebate'; whereas, if he refuses to do this, he may be guilty of partnership in a wicked trick or combine. The popular sentiment and legislative forore which condemns at the same time free competition in prices and every agreement to prevent such competition, needs, as President Roosevelt has in substance frankly declared, to be modified by common sense.

But we are now concerned with the ethical or legal problems of the manufacturer. From the standpoint of the engineer, acting as purchasing agent or adviser, the case seems as clear to me in a court of honor as it would be in a court of law. He cannot honorably accept a commission from the seller while he is the agent of the buyer. If the custom of the trade permits the giving of such commission, but not its deduction from the face of the bill rendered, he may, of course, honorably accept it and pay it over to his own employer—that being the only way in which he could secure the minimum net price in his employer's interest. But even in that event, he should place his honor above suspicion—as, for instance, by commanding the commission in a check to his own order, and endorsing the same check to the order of his employer. There may be exceptional cases in which the taking and keeping of a commission is justifiable, but one thing is clear beyond dispute: it is always wrong when it needs to be kept silent.

It seems almost superfluous to insist upon the duty of maintaining a spirit of loyalty toward employers. Yet this spirit is by no means as prevalent as a sense of honor, or even of enlightened self-interest, would demand. Loyalty to a corporation should be as unquestionable as to an individual. In neither case should it be sacrificed to feelings of personal resentment or disapproval. If one cannot 'stand for' the policies or practices of one's employer, the straightforward course is to seek employment elsewhere.

There are two special spheres in which the mining engineer, like the members of other technical professions, maintains a double relation. One of these is that in which, being himself an employee, he exercises the employer's authority over other employees. In such a position, while it is his duty to protect vigilantly his employer's rights and interests, he should realize that he cannot do this more effectively than by invariable justice, good nature, respect, and sympathy toward his own subordinates. Nothing contributes more toward the success of an enterprise than the mutual exercise of these feelings between workmen and superintendents or managers. It is the 'team work' that wins in industrial undertakings as well as in the athletic field. And in these days especially it is the cultivation of an esprit de corps based upon truly friendly personal relations, which offers the best protection against the schemes of mischief-makers and demagogues.

The other double relation to which I have alluded is that which is occupied by an expert witness in a court of law. In this case he is, theoretically amicus curiae, a friend of the court, giving under oath his assistance in the recognition and interpretation of the facts of the case; and, for this reason, he is permitted to do what no ordinary witness can do, namely, to give opinions as well as personally observed facts, and to support these opinions by hearsay evidence or scientific authority and argument, not otherwise admissible as testimony. Yet, on the other hand he is retained and paid by one of the litigant parties; and he would not appear in court at all were it not reasonably certain beforehand that his testimony would support the theory and benefit the cause of his clients.

The ethics of this situation may be more clearly perceived if we consider that, first and foremost, the expert witness must remember the obligation of his oath. He has not the same latitude as the attorney, whose official duty is to present a client's case without declaring his private opinion about it. Consequently, the expert witness should be thoroughly convinced beforehand of the justice and truth of the cause or the theory in support of which he appears. Such a conviction ought to be based upon a careful and exhaustive previous examination of the case; and no expert should agree to testify in any case until such an examination has established his opinion and qualified him to defend. Concerning some aspects of this question I would here refer, without
further discussion in this place, to the suggestive address of Dr. Raymond, printed in the proceedings of the American Institute of Mining Engineers for November, 1908.

A more simple and congenial, yet more heavily responsible, relation is that which the mining engineer may be called to assume toward the public, as the responsible indorsers of a proposed undertaking. In consideration of the confidence which he invokes and expects, notwithstanding the fact that he has been paid by interested parties, he assumes a sacred trust, obligating him to safeguard the interests of a wider and more important clientele. The investor has not the time, and perhaps not the technical knowledge, required for the thorough study of a prospectus. He risks his money upon his belief in the ability and integrity of the engineer, who is therefore bound, in prudence and in honor, to be specially careful that his endorsement be clear and precise, without mental reservation or opportunity for misunderstanding. This caution applies particularly to what are called 'gilt-edge' investments, that is, to enterprises so promising and so thoroughly investigated beforehand as to warrant their recommendation, on the terms stated, to the general public—that is, to unknown and probably unskilled clients.

There are numerous instances in which the engineer has to give advice on speculative, though honest and legitimate, undertakings, such as the development of mining prospects, which should be confined to those who are willing and can afford to take greater risks, in the hope of larger profits, than pertain to the 'gilt-edge' class of mining investments.

In connection with the class of advisory reports last named, it is good policy for the expert adviser to seek to acquire a special clientele among mining investors who will not be led to judge him by the results of a single case, but, knowing the wisdom and the successful outcome of his recommendations in other cases, will not condemn him when he turns out to have been mistaken. For such a disappointment, sooner or later, is inevitable, since no engineer, however able and careful, is infallible.

In my opinion, a mining engineer engaged in such consulting practice should aim to become himself a capitalist and a purchaser and developer of mining properties. Should he acquire business experience, he might become avowedly a promoter, in a high and worthy sense of that term, and thus assist in driving out the unscrupulous promoters, who are really parasites. According to my observation, the swindling in mining enterprises is done mostly by laymen, and not by responsible professional engineers or practical miners. The practical miner indeed is, in many instances, the victim of the unscrupulous promoter.

As already observed in considering the relations of the engineer to the public, it may also be repeated from the standpoint of his own interests, that he should use the greatest circumspection to prevent the use of his name in support of enterprises of which he has but a superficial knowledge. He may be quite willing to 'take the chances' and invest some of his own money in a scheme which he would not be willing to take the responsibility of recommending to another party, dependent upon his judgment as a guide. But even such a private investment of his own money should often be avoided, lest his connection with the scheme as a simple stockholder should be construed as implying his deliberate indorsement of it as an expert.

It often happens that an expert who has won deserved reputation and public confidence is called to give advice concerning a district with which he is not personally acquainted. In such a case his honest off-hand judgment, based upon general knowledge and upon experience elsewhere, might mislead both himself and others. Yet it is practically impossible for an expert, visiting a given property or district for the first time, and, of course, known to all as the possible 'advance agent' of capital, to get at the unfavorable conditions which it is everybody's interest to hide. I would earnestly recommend, in such cases, the engagement by the examining expert, at his own selection and cost, and without notice to any other party, of a local expert assistant, familiar with the conditions and history of the property concerned and of the district in which it lies—in other words, with those facts which a visitor cannot really discover.

I am fully aware that these desultory remarks have covered but a small part of the field of professional ethics, even in a single branch of the profession represented by the Institute. But I am not offering a code, or even an official and representative declaration of principles. My remarks are intended, and will, I hope, be accepted, simply as a contribution to that discussion of their theme in which every engineer of experience may participate.

**IRIDIUM INSTEAD OF PLATINUM FOR CRUCIBLES.**

Sir William Crooks has been experimenting with wrought iridium crucibles for use in ordinary chemical analysis, instead of platinum crucibles. He gives an account of the results obtained in a short memoir published in a recent issue of the *Proceedings of the Royal Society*. Iridium is as hard as steel, and does not blister or alter in weight when repeatedly heated to redness. Prolonged heating in a Bunsen flame with a yellow tip has no action on the crucible other than to temporarily smoke it, nor does gas high in sulphur injure it. Boiling aqua regia is without action upon the metal, and phosphates at a red heat in the presence of a reducing agent do not affect it. The metal shows no tendency to alloy with lead or zinc at their boiling points, nor with molten nickel, iron, or gold. The crucible when cleaned after the foregoing metals have been melted in it shows no change in weight. Prolonged heating with copper makes the crucible brittle when hot. Fused caustic alkalies attack the metal, but less markedly than they attack platinum. Rhodium crucibles were found to be almost equally resistant and to have the advantage of greater cheapness, while they possess only about half the weight. Sir William Crooks has put the crucible to a more severe test than any analyst is ever likely to give it.
DETERMINING THE TRUE MERIDIAN.

Written for the Mining and Scientific Press
By A. W. Warwick.

A simple and accurate method for the determination of the true meridian, such as does not involve the use of watches and clocks nor necessitate knowledge of geographical position, seems to warrant publication. During the last few years I have been acquiring a number of mine titles in Mexico, where all surveys must be in accordance with the true meridian. It soon became evident that, except for rough work, the ordinary published methods failed with the regular mining transit in the remote regions where the work was done, for the following reasons: 1. Mean solar time could not be determined (a) owing to the high meridian altitude of the sun for six months in the year, reaching 89° 30' in June, (b) owing to the latitudes being unknown, time could not be determined off the meridian. 2. To get telegraphic time often involved four to six days' ride, with consequent time-error due to jolting or accident, besides the change due to the regular time-rate of the watch. 3. Observation at elongation of Polaris is sometimes impossible in the spring and autumn months owing to both elongations occurring in daytime. A number of methods exist for obtaining time roughly, but these are not satisfactory as a basis for determining the meridian, even when using Polaris near elongation. Later I resorted to straight astronomical methods, by finding sidereal time, converting to mean solar time, making the watch correction, calculating the hour-angle of Polaris, and correcting for azimuth. While this gives the array of figures and conversions so dear to the heart of the computer, they are really all unnecessary, besides requiring a Nautical Almanac, which is not always available. The method that I finally evolved obviates reference to faulty watches or any calculation whatever, and by reference to a single table will give the azimuth correctly within a minute. Latitudes is also correctly determined, as well as time, within a few seconds, at practically any hour of the night. To make the method more striking, no knowledge of geographical position is necessary, or really any knowledge of astronomy, as the stars are found automatically beyond any possibility of doubt by means of the transit.

Table 2 herewith given was computed for stars convenient in latitudes 25 to 30° N and for the year 1908. It can be used for other latitudes and other years by means of coefficients given in Table 1. Table 2 gives all the elements for determining azimuth as well as all data necessary for finding the stars and for determining latitude. Some convenient notes are given for selecting the stars to be used. Before giving examples of its use or demonstrating the accuracy of the method, it may be well to explain briefly some of the terms.

The term right ascension (R.A.) is a constant bugbear to the young surveyor. Consider it as sidereal time and most difficulties vanish. A sidereal day is the interval of time between the two successive upper transits of a fixed star. This interval of time is divided into 24 hours of sidereal time. There must be a zero or 24 o'clock. This zero is the vernal equinox which, just like a star, transits (or crosses the local meridian) every 24 sidereal hours. Then when we find in the table that Sirius (or Alpha Canis Major) has a right ascension of 6 hr. 41 m., it simply means that when Sirius is on the meridian of the place of observation the sidereal time is 6 hr. 41 m. The R.A. of Polaris is now 1 hr. 26 m.; that is, it is on the meridian at 1 hr. 26 m., according to the sidereal clock. Therefore, when Sirius is on the meridian Polaris has passed it 6 hr. 41 m., minus 1 hr. 26 m., or 5 hr. 15 m. earlier. Thus the hour-angle of Polaris is 5 hr. 15 m., sidereal time, when Sirius is on the meridian of the place. The orbit of Polaris around the pole is accurately known and from the hour-angle its azimuth can readily be calculated.

In the method used, only sidereal time is employed, since to convert it into mean solar time, and then use watches or clocks, is merely to re-introduce perfectly useless complications. The transit of a star is observed, the R.A. is then the local sidereal time, which is immediately used on Polaris, and the azimuth correction given in the table is laid off without any calculations whatever. Of course, at one, the query arises how is the time-star to be found among the countless host without a thorough knowledge of astronomy? It is perfectly easy. The approximate latitude and meridian are to be determined just before the observation of the time-star, as explained later. The telescope is laid approximately in the meridian across which the star is to transit. The altitude of the southern time-star is found by adding its declination to the latitude and subtracting from 90°, or

\[ \text{Alt.} = 90° - (\text{dec.} + \text{lat.}) \]

Setting the vertical arc to this angle with the telescope in the meridian pointing south, no other star of the magnitude of the time-star will be seen for a long time before or after its transit. Hence no doubt can be felt as to the identity of the star observed. Simple instrumental adjustments will find the star sought beyond any possible doubt.

In order to select the star for observation the suritable elements are given in the table which is laid off.
veyor will find in Table 2 the mean solar time of
transit for the first of the month at those dates when
each star is convenient for early morning or evening
observations. Thus, if we wish to observe in the
A very convenient method of choosing a star is
by directly reading the stars themselves with the
eye. In the circumpolar constellations we have Cas-
siopeia and Ursa Major (the Big Dipper), an excel-

</table>

For each day previous to the 1st a star will transit 3.93 minutes later & for each day after 3.93 minutes earlier: thus β Ceti will transit Dec 15th. 3.93 x 14 = 55° earlier or at 7:05 mean solar time.

Table 2.

evening during December, two stars in the constel-
lation Cetens are available (β Ceti or ε Ceti), Beta
transiting 47 minutes before Polaris and Zeta 21
minutes after. If in the morning γ Corvi, or Spica,
might be used.

When Polaris is at its upper culmination the con-
stellation Cassiopeia will be vertically above it and
Ursa Major vertically below. Cassiopeia then forms a brilliant marked M of stars as bright as Polaris. A vertical line will pass between the last two stars of Cassiopeia, down through Polaris and between the first and second stars in the handle of the Dipper. It is then 1 hr. 26 m. sidereal time. The first quadrant west will be made six hours later, or at 7 hr. 26 m. sidereal time. Ursa Major will lie vertically above and Cassiopeia vertically below Polaris 12 hours later, or at 13 hr. 26 m. sidereal time. Cassiopeia will be in the last quadrant 18 hours later, or 19 hr. 26 m. sidereal time. When Cassiopeia is at A.B.C.D., the times will be 4 hr. 26 m., 10 hr. 26 m., 16 hr. 26 m., 22 hr. 26 m., respectively. Therefore the line mentioned is used as an alidade, the end terminating in Cassiopeia, giving on the circular path of that constellation the approximate sidereal time. With hardly any practice this dial can be read to within 15 minutes of sidereal time or right ascension. Without any reference, therefore, to the Nautical Almanac, or to a badly running watch, local sidereal time can be read at once. If the circumpolar stars

show 4 hr. 26 m., for example, about the time of observation a star is selected with a right ascension sufficiently great to allow a good set-up of the transit. Rigel, coming on the meridian at 5 hr. 10 m., is a suitable star, allowing forty minutes for error in reading the circumpolar stars and for time to set up the instrument. If a gross mistake has been made a Leporis transiting 19 minutes later and a Columbus, 26 minutes later, can be used.

With these explanations the method for determining the true meridian can be readily followed. It is assumed that the instrument is in good adjustment. If not, the observation must be made near elongation, when the horizontal component is changing slowly, in order to be able to use the familiar method of reversals to eliminate instrumental errors. It is highly desirable to adjust the instrument, however, in order to be able to get correct time with direct observations.

The following operations are carried out:

1. Having set the instrument over a hub on the south end of a line with a clear view to the north of about 500 ft., read the circumpolar stars and get approximate sidereal time. Select a star that does not require a tedious wait.

2. With the verniers at zero, set on Polaris with the lower motion. Read the vertical angle. Set off the azimuth called for by the sidereal time, and apply the latitude correction to the vertical angle. These corrections are given in the table.

3. Plunge the telescope or move the instrument exactly 180° in azimuth. Set the telescope at an altitude of 90°—(declination of time star + latitude).

4. If the star has been well selected, it will be near the meridian. It will be in the field of vision about two minutes before crossing the vertical hair. When the star reaches the field of vision, it is followed in altitude by the tangent-screw of the vertical arc.

5. When the star is on the vertical cross-hair the vertical arc is read rapidly. The telescope is plunged or turned 180° in azimuth. The upper motion is unclamped and the plates set at zero. The vertical arc is once more set at the altitude of Polaris, which will be again in the field of vision. Set the star on the cross-hairs by the vertical tangent-screw and the lower motion. Read the vertical angle for latitude.

6. From the table, take out the azimuth correction and set off in the usual way. Correct the vertical angle by the latitude correction given, which also includes refraction correction.

The following example shows the working:

December 15, 1907, Pino Alto, Sinaloa. Local mean time. 6:45 P. M. Sidereal time, about 9 h. 25 m. Time-star β Ceti: R.A., 9 h. 39 m., Dec. = 18° 30'. Az. corr. = 18'. Lat. corr. — 72'. Vertical angle of Polaris, 25° 02'.

Vertical angle • • • • 25° 02'
Correction • • • • 1° 12'

Latitude • • • • 26° 50'

Calculated Altitude of β Ceti:

<tr>
<td>Altitude</td>
</tr>
</tbody>
</table>

Second observation on Polaris:
Correct azimuth correction: + 18°
Altitude: 27° 57'
Correction for azimuth, set off to the west 18 minutes.

Observed latitude on β Ceti:
25° 02' = 26° 46' — 1° = 25° 44'

Observed latitude on Polaris:
27° 57' — 1° 12' = 26° 45'

Computed time of transit: 7 h. 05 m.
Watch time: 7 h. 06 m. 30 s.

Approx. watch error: 1 m. 30 s.

The error of the meridian line thus set out will be less than 1 minute, in spite of a considerable error in the meridian line set for the determination of time. The following calculation will demonstrate this: The time elapsed between the observation on β Ceti and Polaris was 21 minutes. The observation was made near culmination when Polaris was chang-
ing 0.43 minutes of arc for each minute of time. The error of the meridian line was, therefore, 9 minutes of arc. The resulting time-error can be calculated from the formula:

\[ \text{Time error in sec.} = \frac{\sin(\text{lat} - \text{dec.})}{\cos \text{dec.}} \times \text{Az. error in sec.} \]

The error of time was, therefore, 32.8 seconds. Now as even at culmination it takes 2.5 minutes of time to cause a change in azimuth of one minute, an error of 33 seconds is absolutely negligible for our purposes, as the induced azimuth error is less than 15 seconds. As a matter of fact, if the time-observation be made within half or three-quarters of an hour after setting on Polaris, and without first making a partial correction for azimuth, the final azimuth error is less than a minute. The following table shows this clearly:

<table>
<thead>
<tr>
<th>Hour-Angle</th>
<th>Polaris</th>
<th>Meridian error</th>
<th>Azimuth error</th>
<th>Time required to cause change of azimuth</th>
</tr>
</thead>

</table>

Thus, if we use a meridian line 1° 20' in error the time-error is only 5 minutes. As Polaris is moving so slowly in its horizontal component, even a 5° error of time will not cause an error of 1° of arc. By the method given the time-error will never exceed 35" and near elongation it will be in error less than 5" if the instrument be in adjustment.

Should there be any doubt as to the adjustments of the instrument, the familiar method of reversal can be used, observing the time-stars as they come to the meridian. There is rarely, however, any excuse for having the instrument in such bad adjustment that the surveyor has to spend hours in making a correct determination of the true meridian. The time thus wasted would be more profitably spent in adjusting the instrument.

In order to get time correct enough for watch adjustment, simultaneously with latitude and azimuth, I slightly modify the method given. If the telescope in a meridian slightly west of north and east of south, the time observed on a southern time-star will be fast. Therefore, the first observation is made so as to get time about 5° fast. Using this closely approximate time, the telescope can be laid in the meridian within a minute or two. Sidereal time is then determined within from 3 to 5 seconds, and the meridian determined far within the limits set by an instrument that reads only to the nearest minute.

In the table given + in the azimuth correction means that Polaris is east of the meridian, and of course — means that it is west. The latitude corrections are applied direct to the altitude according to the algebraic signs.

The working of the method is simple and requires no special skill. A little practice will enable the surveyor to recognize, by simple inspection, every star used, and thus enable him to select the star that will soonest come to the meridian, thereby avoiding long tedious waits and allowing the work to be done in a reasonably short time.

The mineral production of California during 1907 is given by the State Mineralogist as $55,697,949, being an increase of $8,921,864, or 19%, over that for 1906. The detailed statement of the principal minerals contributing to this total is as follows, arranged in order of relative value of the products:

The feature of the year was the advancement of petroleum to the first place, surpassing gold in the value of output for the first time. The production of gold and silver fell off $2,070,708 in 1907, as compared with the preceding year. Metallic substances, including precious metals, represent $24,896,083, which is a decrease of $1,206,619 as compared with the production of 1906. The decrease is less than in the case of precious metals.

The production of chrome ore in the United States is an insignificant figure when compared with the consumption, the total output in 1907 amounting to but 290 long tons, valued at $5640. The maximum production of any one year (1894) was 3680 long tons, valued at $53,231. This value was, however, slightly exceeded in 1890, when the output amounted to 3599 long tons, valued at $53,955. The demand is supplied from foreign sources, chiefly Asiatic Turkey and New Caledonia, and the imports during 1907 amounted to 41,899 long tons, valued at $491,925.

The total capacity of prime movers in the United States in all classes of land industries for the year 1908 is estimated by H. St. Clair Putnam, in a paper recently read before the American Institute of Electrical Engineers to be 30,000,000 horsepower. It is probable, however, that the total average load does not exceed one-third or one-quarter of this amount.

The tangent of one second is 0.000000485, or roughly, 5 zeros and a 5. This makes a convenient rule for finding the tangent or sine of small angles, since for angles less than one minute the sine and tangent are approximately directly proportional to the value of the angle, and of course the sine and tangent are of the same numerical value.
AMARILLA IRON AND PHOSPHATE DEPOSITS.

Written for the MINING AND SCIENTIFIC PRESS
By OSCAR H. HERSHEY.

The Amarilla group of seven mining claims is situated on the eastern slope of the Cortez range, about six miles westerly from Lane’s Crossing on the Eureka & Palisade railroad, in Eureka county, Nevada. The present title to these iron claims dates from their location, between June 24 and July 30, 1905, by me for M. L. Requa; they subsequently came into the possession of the White Pine Exploration Co. The name Amarilla was suggested by the fact that the best deposit was nearly covered by yellow flowers. The altitude is about 6900 ft. There is no timber in the range except small groves of cottonwood near many small springs in the gulches. The climate is delightful in summer and not very severe in winter, so that there would be no difficulty about carrying on mining in open-cuts all the year.

The Cortez range in the vicinity of the Amarilla property consists chiefly of Tertiary rhyolites, apparently in a succession of thick sheets. As I have not visited the locality since 1905, and as my reports were destroyed in the San Francisco fire, I cannot specifically describe the lavas; some of the sheets may be more basic than rhyolite. Within the series there is a moderately coarse light brown and red sandstone. It is rarely more than 100 to 200 ft. thick, but in the vicinity of the Amarilla property it attains a thickness of over 700 ft. The old Paleozoic basement is nowhere exposed in this portion of the range, and is probably deeply buried under these Tertiary sediments and volcanics. The latter have been tilted at many angles and deeply cut by the erosion of gulches. The iron and phosphate deposits occur in the first thick sheet of rhyolite above the sandstone. The iron ore of commercial grade is a fairly compact, fine to medium grained, black crystalline hematite, that outcrops prominently in places, and in others weather to a dark red soil. Fine-grained quartz occurs in seams, and there are small inclusions of altered rhyolite at many places in the ore. Small yellow crystals of apatite are present in all parts of it. There are six important bodies; the prevailing shape is that of an inverted canoe. On the basis of the vertical range of the outcrops I estimated them to contain as follows:

Tons

Amarilla No. 1 ........................ 375,000
Amarilla No. 2 ........................ 750,000
Alameda ................................ 95,759
Costra Costa .......................... 250,000
Capitola ................................ 63,759
San Diego ............................. 15,425

Total ................................... 1,548,125

Subsequently, an adit was driven to pass under No. 1 orebody, and it has demonstrated that this orebody at least extends much deeper than at first assumed. Fourteen samples showed an iron content ranging from 47.30 to 60.10%, and averaged 56.26%. A partial analysis made by H. A. Ross of a selected sample that assayed 63% iron, yielded free silica 5.67, lime 0.70, phosphoric anhydride 1.26, and combined water 1.18%. Another sample yielded 9.90% insoluble silica, and other tests indicate that the excess of iron over silica is nearly 50%. Besides these orebodies, there are large masses of lower-grade material; some is a breccia of altered rhyolite in rather large fragments cemented by hematite; other large bodies are soft, earthy, impure hematite ore, assays on which range from 41 to 47.40% iron. There is practically no gold and silver present in the iron ore, although traces of gold are sometimes found in assaying. Cutting the rhyolite in various directions near the orebodies are veins of fine-grained quartz and hematite that usually yield traces of gold and silver. One on the eastern border of Amarilla No. 1 orebody assayed 40c. gold per ton. They were not usually assayed for iron, but a 2½ ft. flat-lying vein at the contact between the sandstone and the overlying rhyolite contained 42% iron. The relatively high phosphorus content prevents the iron ore from being attractive at present for the production of iron, although in parts of Europe it would be smelted and the phosphorus recovered as a by-product. Its isolation in a sparsely settled country, the scarcity of fuel, and the high transportation charges are against it; but it has a possible present value for flux. A much smaller deposit of similar character has been mined for years at Barth, on the Central Pacific railroad, and shipped to the smelters for that purpose. To make the Amarilla deposits available it will be necessary to build a 7-mile spur to the narrow-gage Eureka & Palisade railroad. This spur will ascend a small valley, rising from 5150 to 6250 ft. above sea-level, and may cost $35,000. It is only a question of a little time before the value of these deposits as a source of iron will be recognized. The rhyolite inclusions, and the large bodies of rhyolite in the vicinity of the iron, have been highly altered and contain a rather unusual grouping of contact-metamorphic minerals. Fairly large distinct crystals of a yellow mineral were found in the rhyolite of the Monterey claim, and were submitted to A. C. Lawson of the University of Califorina, who identified them as apatite.

While having the location work done on the iron deposits, I became interested in obscure outcrops and loose fragments of a rock which at first I thought was sandstone, but when the sun shone on it a peculiar glitter suggested reflection from crystal facets. Later I found some sufficiently coarse to enable me to distinguish apatite crystals with the unaided eye, and it became apparent that all of this supposed sandstone was fine-grained apatite rock. It occurs in bodies near but distinct from the iron orebodies and in strips like veins from 5 to 10 or more feet wide, traversing the rhyolite. Selecting the largest outcropping body, I had two shallow trenches, 80 ft. apart, dug down to rock in place, and sampled the better-looking strips. The west branch, 109 ft. long, cut 25 ft. of iron and apatite that carries 9.62% P₂O₅; then 20 ft. of apatite rock that carries 14.38% P₂O₅; then 25 ft. of apatite, quartz, and iron; then 30 ft. of fine-grained apatite rock with 15.70% P₂O₅; and finally 9 ft. of rhyolite. The east trench, 91 ft. long, cut 2 ft. of iron ore, then 11 ft. of apa-
tite rock that carries 13.28% \( P_2O_5 \), followed by 13 ft. of similar rock that contains 12.18% \( P_2O_5 \), and finally 40 ft. of rhyolite and iron ore.

In the west trench a width of 50 ft. averages about 15% phosphoric anhydride. This is much higher grade material than the average of all the apatite deposits in Canada that were mined a few years ago, but is only about half as rich as it should be to have commercial value (without concentration) in the western part of the United States. A sample that contained 12.8% phosphoric acid was submitted to George E. Colby, of Berkeley, California, who stated that such rock was not rich enough to treat with sulphuric acid for the commercial production of superphosphate. If about 8% of soluble phosphoric acid were produced by the treatment, the extraction and concentration could not be economically accomplished. The large amount of iron and alumina prevents its being satisfactorily treated with sulphuric acid to convert simple phosphate into superphosphate. The iron and alumina would so combine with the soluble phosphoric acid produced by the sulphuric acid treatment that it would render it insoluble. The iron and alumina should not run over 3% in the concentrated material. At present there is no economic necessity to search for a method of concentrating this deposit. Rock yielding 30% phosphoric anhydride has been shipped from southern Idaho and northern Utah to California, and higher-grade rock is brought across the Pacific Ocean from an island on the other side. The Idaho-Utah deposits of 30% grade are said to occur in seams and small bodies. An important manufacturer of superphosphate in California says that if such a large body of 15% phosphate rock as described in this paper exists in Nevada and can be concentrated to 30% material, it may become valuable. I estimated, on the basis of the outcrops, that the Amarilla group of claims might contain 500,000 tons of apatite-bearing rock that might range from 12 to 16% phosphoric anhydride.

These deposits have many of the characteristics of contact metamorphic deposits, but they occur in the igneous rock instead of in the older rock. Whence came so much iron and phosphorus? It is difficult to conceive that more than 850,000 tons of iron have been gathered from the apparently nearly barren rhyolites of the range. I believe that the iron and phosphorus may have been derived from the sandstone formation that underlies the iron-bearing rhyolite. This sandstone is highly ferruginous and probably also phosphatic. It was formed during middle Tertiary time, a period favorable to the production of phosphatic lime elsewhere in the United States. The outcropping sandstone in the immediate vicinity of the Amarilla property is not leached; in fact, iron appears to have been added to the upper few feet of it. It seems probable that the rhyolite in a thick sheet flowed down the gently inclined surface of the sandstone, either in the lake or after the lake had been drained. It heated the water in the sandstone and perhaps to this was added hot water emanating from the lava. Thus the iron phosphate and silica could have been leached from the sandstone and would rise into the lower portion of the flowing lava to their present position. Some of the phosphate remained throughout the iron ore, but most of it was expelled (along with silica and some iron) and formed separate bodies and vein-like masses near the iron-ore masses. After the mass had become fairly solid, shrinkage cracks opened through it. The deeper portions of the iron orebodies were still expelling iron and silica in hot solution. These minerals rose in the fractures and were deposited as hematite-bearing quartz-veins in which are traces of gold and silver. Finally, in the last stage, the iron orebodies were slightly cracked and silica was deposited in the cracks, forming fine-grained quartz seams.

**Bond** in reinforced concrete beams has recently been investigated at the University of Wisconsin, and the results were reported and discussed in a paper read before the American Society for Testing Materials. The beams tested were in general 5 ft. 6 in. long, 5 in. wide, and 6 in. deep. They were so made that the central portion of the lower rod, the bond of which was to be obtained, was exposed. Two ¾-in. round rods were placed above the exposed bar to distribute the tension-cracks and prevent failure in the concrete before the lower rod slipped. The embedment at each end was 10 inches in all but three instances. The conclusions arrived at from a study of the data obtained are as follows: 1. The bond of 1:2:4 concrete to embedded steel increases with age at least up to six months. About 80% of its six months’ bond-strength is developed at 28 days. 2. Owing to the variation in results of the one-month tests, and the wide difference between laboratory experiments and practical working conditions, it does not seem as though the maximum bond of 1:2:4 concrete should be assumed greater than 200 or 250 lb. per square inch in designing. 3. The method of making bond tests by pulling a rod from a concrete cylinder, heretofore the usual method, gives results which are of neither quantitative nor qualitative value. A comparison between the bond developed in beams and that obtained in bond cylinders made at the same time shows that the cylinder tests gave bond stresses from 1.42 to 2.99 times as large as those obtained from the beam-tests. This indicates that the ratio of bond in cylinder to bond in beam increases with the compressive stress applied to the top of the bond cylinder. 4. The beam test for bond, on the other hand, approaches closely the actual conditions to which the bar and surrounding concrete are most often subjected, and gives values which are at least of qualitative value. Furthermore, values obtained by this method are in accord with the bond theory usually accepted as a basis in design.

**Shasta** heads the list of California counties in the production of silver during 1907, its output being more than 49% of the total.

**Belt-driven power pumps** are more efficient than steam pumps when a small amount of water is to be raised.
A CENTRAL COMPRESSED-AIR SCHEME.

Ever since central power stations were first mooted on the Rand, far-seeing engineers have been debating the possibility of extending the principle of centralization to the costly and admittedly inefficient compressed-air plants. Today a scheme to establish central air-stations, which has been two years in the making, is on a fair way to be definitely realized. With its power-supply plans, the newest centralized electric power company proposes to include compressed air, the object being to relieve the mines from necessity to generate either form of power for themselves by the comparatively extravagant old-fashioned methods. What one power-supply company can do, no doubt the other companies can and will also do.

The engineering features of the new scheme are full of interest. In several particulars the world-renowned Paris compressed-air system will be followed in the design of the plant, but the Paris plant will be improved upon and advantage taken of the discoveries of modern practice and research. The Paris plant is driven by steam-power. The Rand plant will be driven by electric-power drawn from a central power-station. The compressors will be of the vertical displacement type of 5000 hp. capacity each, three-cylinder, two of low pressure, and one of high. Each compressor will have two 2500-hp. motors direct-connected to the crank-shaft. The motors will be coupled together, so that they can run at full or half-speed without altering the number of poles. Any variation in the output of air required below these two variations of speed will be dealt with by means of inlet-valves of the Corliss type, operating by trip-gear controlled from air-pressure. In view of the experiments now in progress on the mines to determine the utility of high air-pressure, the compressors will have a working pressure of from 80 to 110 lb. per sq. in., the pressure between these figures being dependent, of course, upon the requirements of the mines. The intention is to start with two chief stations on the Central Rand, one being situated in the Fordsburg neighborhood, the other at a point half-way to Germiston. Later, as other areas develop, additional stations will be established at central points. All these stations will be operated from a central electric-power station. In the light of recent investigations into the question of air-pipe dimensions, it is noteworthy that the pipes to be used on the proposed scheme will vary from 28 down to 11 in. diam. Joints will be electrically welded, without flanges, threaded socket-couplings, or expensive expansion joints. The air will be measured by meter at the mines, and the latter will pay by weight for the amount consumed, the power actually used only being charged for.

At one time it was considered more economical, owing to the saving in the outlay on pipes and the maintenance of a uniform pressure in the mine, to transmit the air at a high pressure of 200 lb. and upward to receivers at a sub-station capable of storing energy for a large number of drills for an hour, and then to reduce the pressure by means of reducing-valves before entering the service-pipes to the mines, to the usual working pressure. This method has, in the light of recent practice, been rejected.

With pipes of proper size and in good condition, air may be transmitted, say, ten miles, with a loss of pressure of less than one pound per mile. If the air were at 80 lb. gauge or 55 lb. absolute upon entering the pipe, and 70 lb. gauge or 85 lb. absolute at the other end, there would be a loss of little more than 10% in absolute pressure, but at the same time there would be an increase of volume of 11% to compensate for this loss of pressure, and the loss of available power would be less than 3%. With higher pressure, still more favorable results could be shown. As a competitor with electricity in long-distance transmission, it seems almost like heresy to claim equal if not greater efficiency; nevertheless it is claimed that within the 20-mile limit compressed air will compare in efficiency with electric transmission, while so far as operating and maintenance expenses are concerned, an electric proposition is not to be compared for a moment with that of air. Over 15,000 hp. of compressed-air is distributed today throughout the city of Paris, being transmitted for a series of stations from three to fifteen miles distant, with a loss of 10-lb. pressure in transmission. An essential requisite of a successful central air-compressor scheme is cheap electric power. The guarantee of this in the case of the Rand assures the commercial success of the project.

The National Forests are constantly patrolled by a picked force of rangers and guards. The present summer force of such rangers and guards, whose main duty is fire patrol, is 1351 men; the average area that each is required to protect is 121,506 acres.

This area is altogether too large, and as soon as funds are available to permit of the employment of a larger force of men the area per man will be reduced. In order to provide rapid means of travel between the various parts of the National Forests, and to facilitate the massing of large forces of men to fight fire, as well as to furnish vantage points from which the fires may be fought successfully, 160 miles of road and 3300 miles of trail were built during the last fiscal year. In several cases fire-breaks from 16 to 100 ft. wide have been constructed, from which all timber and inflammable material was removed. Several miles of such fire-breaks now exist on the National Forests in southern California, where it is especially important that the forest-cover on the watershed of important irrigation streams be protected.

Telephone lines have been constructed connecting ranger stations with the headquarters of the forest, in order that fires may be reported and promptly extinguished. During the fiscal year ending June 30, 1908, 3500 miles of telephone wire were strung in the National Forests.

Californite is a compact variety of vesuvianite with color and texture so like jade that it was at first mistaken for that mineral. It is found in Siskiyou county, Cal., on the south fork of Indian creek, 12 miles from Happy Camp.

*Abstracted from South African Mining Journal.
THE FINGER-CHUTE.

Written for the Mining and Scientific Press

By T. A. Rickard.

In mines producing a large tonnage of low-grade ore, the handling of the material broken in the stope becomes a problem of prime importance. From the stope itself the ore has to be transferred to the cars on the main level. This transfer is effected by gravity wherever the conditions are favorable; where the dip of the lode is so flat as to render automatic descent impracticable, the assistance of an elastic traction system, such as the 'mono-rail' at Johannesburg or the 'go-devil' at Grass Valley, is invoked.

The methods in vogue in the great mines at Treadwell, on Douglas Island, Alaska, have many features worthy of record and of imitation. The pillar system of excavation was described in the issue of July 18 of this journal. Another detail in the local practice as developed by the management is the use of the 'finger-chute,' a device for expediting the descent of the ore into the cars.

The finger-chute was first used, as far as I can learn, in the El Callao mine, Venezuela, and was brought to the Alaska-Treadwell by Mr. H. C. Perkins, probably. Wherever originated, this device has been brought to perfection by the successive superintendents of the Alaska-Treadwell mine, and it has become a distinctive feature of their underground operations. The finger-chute is designed to serve stope yielding ore that is broken in large pieces of irregular shape. As used several years ago it was described by Mr. Robert A. Kinzie in the Transactions of the American Institute of Mining Engineers, Vol. XXXIV, under date of 1904. But changes have been made since then, by Mr. McKinzie and his assistants, with a view to diminishing the wear and tear, thereby lessening the cost of maintenance; also one or two minor, but important, modifications have been made in the details of the mechanism. A drawing is given herewith, and a good photograph taken by flashlight underground.

Instead of having the ordinary solid door, whether of iron or wood, the chute is closed by means of six 'fingers,' made of 4 by 6 inch timbers, faced with iron. These fingers can be operated independently, one at a time or all together, so that if a piece of ore chokes the outlet, it is easy to look between the fingers and see what is causing the obstruction. Thereupon, such of the fingers can be lifted as will permit a man to use a crow-bar with advantage; meanwhile, the other fingers will prevent a sudden rush of rock. In case the manipulation of a bar proves ineffectual,
long. See accompanying drawing. The fingers are bolted and braced so as to make a strong construction, and the parts exposed to wear are armored with thick sheet-iron. In the knuckle of the finger there is a hole (1½ in. diam.) through which passes an iron pipe, serving as an axle, on which the fingers can be moved up and down. To the extreme end of the long and (when at rest) nearly horizontal arm of the finger, a chain (9/16 in. iron) is attached, the other end being fastened to a ring. This ring holds the chains from all the fingers. From the ring a chain passes over a sheave (8 in. diam.) down to a windless on the side (and 2 ft. from the bottom) of the level opposite the chute. On the deepest levels of the Alaska-Treadwell mine this windlass is not used at present, but experience indicates that it will be needed as the stopes become enlarged. By means of the windlass and sheave, one man can readily raise all of the fingers. An individual finger is moved by pulling a single chain or, more usually, a bar is pushed against the lower end, so as to elevate it, when desired.

The frame of the chute itself is made of heavy timbers, 12 by 12 in., drift-bolted together and blocked solidly against the adjacent rock. Special care is taken to put these timbers firmly in place, so that they will be able to withstand the blasting often necessary to clear an obstruction in the chute due to jamming of the descending ore. The lip of the chute is built of 3-in. plank, the sides having an extra cover of 2-in. plank. Both sides and bottom are protected by 1/4-in. iron plate.

In constructing one of these finger-chutes, the first thing done is to erect the front frame of 12-in. timbers; these are set in hitches cut in the rock and solidly blocked. Then the cross-timbers, which serve as bearers for the sides and bottom of the chute, are placed in position. These also are firmly blocked and wedged against the sides of the opening in the rock. Next, the side and bottom planks are 'spiked' or nailed in place. Brackets are bolted to the front timbers, in order to carry the pipe on which the fingers turn. This pipe is passed through the six fin-

The Finger-Chute in the Alaska-Treadwell Mine.
be closed tightly by means of wooden blocks, firmly wedged. The windlass consists of a wooden roller, the axe of which is a piece of 1½-in. round iron, one end being extended and bent so as to form a crank-handle. The shaft of the windlass is supported and turned through round openings made in the projecting ends of two pieces of 1½-in. iron inserted firmly within two horizontal drill-holes made in the side of the level, as in the case of the sheave. In order to stop the flow of fine material escaping between the fingers, a 6-in. board is dropped in front of the lip of the chute. This board is held in place by an angle-plate nailed to the bottom lining of the lip on both sides.

Two men, at $4$ and $3.50$ per shift, respectively, will erect a finger-chute in three shifts. All the material used in the construction is framed, ironed, and made ready at the surface. An ordinary board-chute requires the labor (in erection) of two men for two shifts, when round timbers are used. Formerly, a roller was used in place of the sheave. The roller required two bearings and was more expensive to install, yet it did not last as long nor work as easily as the sheave. The rope formerly used has been replaced by a chain, which lasts sufficiently longer to be cheaper. The tie-rod holding the posts against the head-block has been eliminated, in favor of wooden wedges at the side.

It is possible to draw 500 tons per shift from a single finger-chute. The cost of the chute as formerly constructed was $123; as now modified and above described the expense is only $78. This includes the cutting of the station, but not the excavating of the raise. It is proper to state that this device is suitable only where the ground is dry and the ore coarse; even at Treadwell it has been found inexpedient to use the finger-chute in the Ready Bullion and Mexican mines, which are neighbors of the Alaska-Treadwell and under the same management; in these two mines the ordinary board-chute is found satisfactory. The finger-chute is eminently a chute that will hold the large and small stuff concurrently or separately, as desired.

Iron has a strong affinity for oxygen, which increases with the temperature to which the former is raised, and the specific heats of the resulting oxides are much higher than that of the metal itself. Therefore, in experiments for the purpose of accurately determining the specific heat of iron, it is necessary to prevent oxidation by the removal of the air in contact with the heated sample under test. This has been accomplished by P. Oberhoffer, in the metallurgical laboratory of the Aschen Technical School, who has described the apparatus used and given the values derived thereby in a recent issue of the Zeitschrift des Vereines Deutscher Ingenieure, which is abstracted as follows by The Engineering Digest. Dr. Oberhoffer employed a modification of Bunsen's ice calorimeter, the test tube of which was connected with a vacuum pump. The iron sample was heated directly above the calorimeter by means of a small Heraeus electric furnace, and then allowed to drop down into the calorimeter tube, which was immediately closed by means of a valve. During the cooling of the sample the pump maintained a vacuum in the calorimeter tube, thus preventing oxidation. As an outcome of these experiments, in which all precautions, such as accuracy in the measurements of temperature, uniformity of heating, and insulation of the calorimeter from external influences, were carefully taken, the following results were obtained:

**MEAN SPECIFIC HEAT OF IRON AT VARIOUS TEMPERATURES.**

If the values in this table are plotted as ordinates at abscissas of their corresponding temperatures, a cooling curve results, in which a sharply defined change of direction (vertically) is noted at about 1200°F., corresponding to the critical point Ar 1. This direction is maintained in general to Ar 2, at about 1350°F., when it changes gradually to a horizontal one, the transition being completed at about 1650°F. The specific heat of alpha iron (magnetic, below Ar 2) therefore increases directly with the temperature (approximately), while gamma iron (above Ar 3, non-magnetic) remains practically constant. Regarding beta iron (between Ar 2 and Ar 3), it may be said that, according to Richard's law, that condition of a substance has the highest specific heat whose specific weight is least. To the minimum specific weight corresponds the maximum specific volume, and consequently the greatest coefficient of expansion. Of the three forms, beta iron has the highest specific heat. The iron used in these experiments was almost entirely pure, having the following composition; the test samples weighed from 1 to 6 grams:

A new plan for storing gasoline or petrol depends upon the fire-stopping property of wire gauze that gives safety to the Davy mining lamp. A gauze tube is inserted in the opening of the can or tank, extending to the bottom, and the orifice is then sealed by a plug held in place by fusible solder. If fire occurs near or around the tank, the solder melts and the plug is blown out, when the vapor escaping through the gauze tube burns quietly without explosion. In a test of the method, 12 out of 17 ordinary cans filled with volatile oil exploded on contact with fire, throwing the burning liquid in every direction, but 12 cans fitted with the safety device failed to explode, and the liquid burned quietly and harmlessly.
MINING AND METALLURGICAL PATENTS.
Specially reported for the Mining and Scientific Press.

The herein described smelting process, consisting in discharging slag and matte from a furnace to a settler, and discharging fine ore into the stream of slag and matte as the same flows from the furnace to the settler.

CONCENTRATING APPARATUS.—No. 898,331. Wilton E. Darow, Sutter Creek, California.

In a concentrating apparatus, a plurality of superposed annular series of stationary tables having collecting surfaces, stationary annular pulp boxes and means to distribute pulp therefrom to the tables, supports upon which the tables rest with their ends extending radially inward beyond the supports, and a centrally journaled water supply with distributing arms extending outwardly over the tables and contiguous to the supports.

A miner's cap having a vizor, in combination with a pad secured to the inner crown of the cap, a sheet-metal casing having a bottom portion conforming to the shape of the cap and ending at the upper crown of the cap and then being doubled upon itself to form a base of double thickness, the upper portion of the casing being bent outward and downward, and secured to the vizor of the cap, the forward vertical portion of said casing having a threaded opening, a frusto-conical reflector within said opening, a lamp carried by said reflector, a fabric pocket having a flap secured to the outer crown of said casing enclosing said base, a battery upon said base and within said pocket, an electric switch secured to the under surface of said vizor, and electric conductors connecting said switch, lamp, and batteries.

A die for sharpening drills and adapted to be secured to the drill head, the same comprising a head block, die members pivotally mounted thereon and adapted to embrace the drill head, and a clamping device carried by the head block and engaging the die members to hold them securely about the drill head.

A pneumatic tool, an air pressure feeding device therefor, and an adjustable extension secured to said device, forming an end support for the tool.

ORE-FEEDER.—No. 899,527. Samuel T. Graham, Los Angeles, California.

An ore-feeder comprising a stationary hopper, a shaft passing through the centre of said hopper, a disk on the shaft below the hopper and covering the lower end thereof, said disk having a concentric friction edge, an arm pivotally connected on the shaft below the disk and extending beyond the disk, a friction block in engagement with the friction edge in advance of the arm, a rigid member pivotally connecting said block with the arm, and means for oscillating the arm.

In a slimes separator, the combination of a tank for the cyanide solution, a settler within said tank, an endless conveyor belt within said tank, upon which the slimes are deposited from said settler, said conveyor belt being movable in upward direction, and means for washing the slimes carried off by said belt.
Decisions Relating to Mining.

MINING—OBSTRUCTING A STREAM WITH TAILING.

A person engaged in mining may deposit tailing in a natural watercourse to a reasonable extent, but he has no right to make such deposit to the extent of diverting the water from the natural channel and causing it to overflow the lands of a lower owner, to his damage.

Salstrom v. Orleans Bar Gold Mining Co., (Cal.) 96 Pac. 292, May, '08.

CONFLICTING MINING LOCATIONS—EVIDENCE.

A third locator of a lode mining claim may introduce evidence which tends to establish the existence of a valid and subsisting location prior to the location which such third locator is asserting.

MINING CLAIM—CONVEYANCE OF PART—EFFECT.

A conveyance of a definite and designated tract of a mining claim owned by tenants in common, giving the grantee the same rights as the grantees had, favors completely such tract conveyed, and the grantees have no interest in a discovery made thereafter by the grantee.

Merced Oil Mining Co. v. Patterson, (Cal.) 96 Pac. 90, May, '08.

MINING—ADVANCES BY STOCKHOLDERS.

Where, in the absence of funds of the corporation, certain stockholders tacitly agreed to, and did, advance funds with which to continue mining operations, this was held not to constitute them a mining partnership, and did not make them personally liable for the debts of the corporation, but were no more than advances to the corporation.

Dodge v. Chambers, (Colo.) 96 Pac. 175, June, '08.

ADVERSE SUITS—EFFECT OF NON-SUIT.

Where a plaintiff in an adverse suit to establish title to a disputed claim fails to establish his claim, he is properly non-suited, and he has no right thereafter to participate in the proceedings. After such a non-suit the hearing thereafter is ex parte as to the defendant, and the presumption is that all proceedings were regular and the judgment for defendant correct.

Loker v. Noll, (Mont.) 96 Pac. 343, June, '08.

MINING CLAIM—DISCOVERY—PRIORITY.

One person located and staked a placer claim on May 25, but made no discovery at the time; and thereafter left to get supplies and necessary equipment to proceed with the development work. In the meantime another person located and staked the claim, and when the first locator returned, on June 9, he found the second locator in possession. The first locator entered peaceably on June 9, built a cabin and proceeded to sink a shaft. During the same time the second locator remained on the claim, living in a tent, and was engaged likewise in sinking a shaft. The first locator found sufficient gold in the shaft sunk by him to warrant him in the further expenditure of time and money in the development of the claim. The location made by the first locator on May 25, unaccompanied by discovery at the time, gave to him no right subsequently to return and take possession of the claim after the second locator had made due location and taken possession for the purpose of exploration. But both locators being in possession by common consent on and after June 8, it became a race of diligence between them to discover gold, and he who first discovered it obtained the prior right. While his discovery did not relate back to the date of his location, yet his location was made valid by discovery and became effective from that date, and gave him the full right to the claim, to the exclusion of all others.

Publications Received.

GENESIS OF METALLIFEROUS ORES AND THE ROCKS WHICH ENCLOSE THEM. By BRENTON SYMONS. Published by The Mining Journal, London. Svo., 495 pp., III. Price $2.50.

The author states in his preface that his purpose is to furnish "a popularly written book, containing and devoid of technical expressions as the nature of the subject will admit," and he proceeds to carry out his intention with modesty and success. Little bits of poetry and occasional poetic touches in the prose lighten even such technical references as are necessary. The illustrations are numerous and good. Even the layman will find himself attracted by the suggestive drawings of things below the surface of the earth. Many of these refer to the classic mining regions of Cornwall and Saxony, so that the American reader will find himself becoming informed concerning localities outside his ken, although American sources of information are in no way neglected. The scope of the volume is indicated by the headings: Genesis of rocks, mountain making, denudation of mountains, sedimentation of strata and ores, metamorphism of strata, formation of ore deposits.

This second volume of an admirable text-book on surveying deals chiefly with the several approved methods of conducting topographic and hydrographic surveys. The book is divided into four parts, the titles of which indicate the character of the subject-matter treated. They are: 'Control of the Survey,' 'Filling in Topographic Details,' 'Hydrographic Surveying and Stream Gauging,' and 'Constructing and Finishing Maps.' The volume is replete with practical hints, sample notes, and illuminating illustrations, notable among which are the examples of topographic drawing properly and improperly executed. The chapter on photographic surveying is particularly instructive. This and Vol. I. should fill a long felt want for a practical text-book on surveying.

COMMERCIAL AND NAVIGATION OF THE UNITED STATES. Annual report of the Bureau of Statistics of the Department of Commerce and Labor, for the year ending June 30, 1907.

Commercial Paragraphs.

THE BUCYRUS CO., South Milwaukee, has recently opened an office at 50 Church street, New York City.

The ASBESTOS MANUFACTURING & SUPPLY CO. announces the removal of its San Francisco sales office to 15 Fremont street. The factory and warehouse is still at 63 Minna street.

El Novitiro is the title of a new monthly publication in San Francisco, devoted to the expansion of trade relations with Mexico. It is handsomely printed, in English and Spanish, and begins with the presentation of much valuable data, including new projects of Mexican law for the fostering of commerce. It is published by W. D. Coffey, at 330 Jackson street.

Catalogues Received.

The HILL CLUTCH CO., Cleveland, has recently issued a reprint of that part of its catalogue P which describes collar oil bearings.

The REVERSE RUBBER CO., Boston, has issued a new catalogue of 33 pages illustrating its line of packings, including some new ones recently put on the market. There is much valuable information contained in the pamphlet, which has evidently been prepared at a great expense. The Company will mail a copy to anyone interested.

EDITORIAL.

TIERRA DEL FUEGO is one of the regions where the dredge has been applied to gold mining. Our London correspondent refers to the meeting of an English company engaged in this kind of digging. Instead of moss on the surface of the ground, they have peat; and this peat is used for fuel.

DREDGING AT OROVILLE has been the subject of proceedings in the Circuit Court. The City of Oroville brought suit against the Indiana Gold Dredging Company, claiming that the channel of the Feather river was being blocked by tailing so as to menace the safety of the people in the valley. The judge modified the injunction granted by the Superior Court so that dredging can proceed under reasonable restrictions.

ANNOUNCEMENT is made that the steamship service between San Francisco and New Zealand is to be resumed in January next. The terminal port will be Wellington, instead of Auckland, and a call will be made at Tahiti, instead of Honolulu. The Union Steamship Company of New Zealand and the Oceanic Steamship Company of San Francisco will cooperate in establishing this new intercontinental service. From Wellington there is an excellent service to the chief ports of Australia.

IN OUR NEWS COLUMNS a mention is made of the big ditch built by the Yukon Gold Company, at Dawson. This is the most important engineering enterprise undertaken close to the Arctic Circle, and the completion of it marks an important point in the industrial development of the Yukon Territory. The ditch is 70 miles long, and will bring 5000 miner's inches of water to the placer deposits on Bonanza creek, enabling the engineers of the Yukon company to exploit the large banks of gravel known locally as the White Channel, a bench deposit that was worked on a small scale in the early days, and from which many fortunes were won. We shall publish a detailed description of this undertaking at an early date.

ON OCTOBER 22 the last steamboat leaves Nome for the 'outside,' meaning thereby the home-places of the men who go north in search for gold. On that date this year the Northwestern will take a full complement of mic operators, engineers, and laborers. Other steamships that preceded will have been crowded, but this, 'the last boat,' will be loaded with passengers whose labors for the season are finished. From then until the middle of June next year Nome will have no communication with the 'outside' world except by means of dog-sleds and horse-stages running over the ice and snow by way of St. Michael, Kaltag, Gibbon, Fairbanks, and
Valdez, where steamship connection is made with Seattle and San Francisco.

From Butte our correspondent writes concerning the organization of an association intended to oppose fraudulent mining schemes. Each member of this new association is required to “pledge his honor as a man that he will so conduct himself in relation to the business of mining as not to reflect unfavorably” upon that basic industry. Legislative enactments by the Assembly of Montana are to be demanded in furtherance of the program to scotch wild-cats. All of this is commendable and, whether it succeeds to the full extent expected, or not, the effect of such cooperation between mining men is to create a healthy public opinion, without which laws and juries are impotent.

Whatever may be thought of the proposal to transfer the ownership of the railroads to the Government, and however people may disagree as to the balance of evil between national and corporate management, there can be no doubt that we are trending toward a partition of the ways. Mr. E. H. Harriman and his associates have recently obtained control over the 6300 miles of the St. Louis & San Francisco railway. This group of capitalists and stock-jobbers now has a dominant voice in the management of 11 railroad systems, aggregating $1,544 miles. In 1880 Jay Gould individually controlled all except two of the transcontinental railroads, and being an unscrupulous gambler, his control ended in disaster for the companies and their shareholders. To some people Harriman is a railroad genius and a practical administrator; to others he is only a stock-jobber and a financial trickster on a large scale. He wrecked the Alton and he gambled with the funds of the Union Pacific; he used his position to aid the schemes of a coterie, and he played with the credit of a great railroad in order to manipulate the stock market. No argument that any socialist orator can bring to the support of government ownership of railroads will be one-half as forceful as the spectacle of a national system of transport controlled by a tricky individual. Mr. Harriman is riding for a fall; the faster he succeeds in his efforts to control competing railroads, the sooner will it become obvious that Federal management is less objectionable than dependence upon a group of predatory promoters, who disregard the fundamental fact that railroad ownership is a trusteeship.

In the last number of Economic Geology appears a vigorous protest, by Mr. T. A. Jaggar, against a supposedly hypercritical attack made by Mr. F. L. Ransome on a recent article by Mr. J. E. Spurr. We published the article that furnished the text for this tripartite controversy, but we do not care to discuss the merits or demerits of Mr. Spurr’s contribution. The fact that we published it suffices to express our opinion as to the usefulness of publication. But we venture to risk further trouble by stating our agreement with a good deal that Mr. Jaggar says. He protests against a hypercritical and intolerant attitude on the part of some members of the Geological Survey at Washington; he even rails “dogmatic officialism” at their heads. And not without some justification. Many a Survey publication is disfigured with notes embodying points of minor disagreement with other writers, and many pages are lacking in cordial acknowledgement to earlier observers whose labor broke the trail for the gentlemen of the Department of the Interior. There is an impression that the geologists of the Survey are profuse in references to the writings of their confrères, while deeming the work of outsiders, such as professors of geology and mining engineers, as unsuitable for mention. There are geologists outside of the Survey; and this is said with the hope of not giving offense. We criticize as a friend.

Deep Leads.

The article on the ‘deep leads’ of Australia will be interesting to many of our readers, for the operation described has some points of resemblance to deep-lead mining on the Forest Hill divide in California and also to drift-mining in Alaska and the Yukon. In the deep valleys of the Yuba and American rivers, it is possible to follow the buried channels under the cover of lava by means of workings that conform to the bed-rock of a prehistoric stream. Shaft-sinking is unusual, save for ventilation. But near Ballarat, in the Australian State of Victoria, it is necessary to reach the layers of gold-bearing gravel by means of a shaft. It is true the deep leads first discovered were mined as shallow placerst until they were traced under cover of the basalt that crowned the river-bank, but these first operations led to the recognition of the fact that the alluvium lay on a bed-rock of basalt, not unlike the cap, and that underneath that second bed of Tertiary basalt there existed another gravel-channel lying upon the basement rock, namely, sandstone and slate of Lower Silurian age. More remarkable still, in the true bedrock of the deep leads were found the croppings of the quartz veins from which by erosion in past time the gold of the gravel had been derived. Thus the Band & Albion mine yielded 519,551 ounces of gold, or $10,000,000, from the deep leads up to 1879, when the richness of the veins in the bedrock became recognized. The shaft was sunk to 1500 ft. and from the quartz, by stamp-milling, no less than $3,000,000 was extracted up to 1888. This was one of the few cases where a vein-deposit was topped by an alluvial deposit, both rich. Another analogy can be made with the drift-mines of Alaska and the Yukon. The gold-bearing alluvium of a deep lead is blanketed by a flow of lava, the product of heat: the gravel of the North is covered under frozen ground, due to frost; in each case the overlying hard layer serves as a roof under which the patient miner digs for the gold concentrated long ago in an extinct river-bed. As regards the metallurgical treatment of the gold-bearing material, it is noteworthy that the Australian miner subjects his gravel to a washing process in a ‘puddling’ machine, which detaches the clay and loosens the gold imbedded therein. The machine is
an agitator, facilitating disintegration of gravel held together by clay. In the deep-lead mines of California the gravel is accumulated and is then crushed coarsely through a stamp-mill, or broken in revolving bar disintegrators, or washed with a jet into a series of sluice-boxes. In Alaska the gravel, thumbed underground by steam or even by wood fires, is hoisted to the surface and discharged into water running over the riffles in successive sluice-boxes. In each case extraction of the gold is easy.

While the exploitation of the deep leads in Victoria has proved a serious disappointment, it is not without hope. The chief difficulty has been the tremendous volume of water that it has been found necessary to pump. The various companies in the Lodden valley have spent fully $7,500,000 in preparatory work without as yet extracting any gold worth mentioning. The Lodden Valley company itself has been pumping from eight to ten million gallons per day for several years without exhausting the reservoir accumulated in the old river channel, which is 800 to 1200 ft. wide. It is pleasant to record that the Government of Victoria has advanced $40,000 to this company to aid work that is deemed of public importance.

A Timely Decision.

A DECISION of more than passing importance has been recently rendered by the Supreme Court of the United States (Farrell v. Lockhart, 28 Supreme Ct. Rep., 681). The case of Lavagnino v. Uhlig, 198 U. S., 443, decided in 1905, has probably done more to unsettle the established ideas of mining law and has provoked more unfavorable comment than any other decision rendered by the 'highest court in the land' on the subject of mining law. In our issues of February 16, June 1 and 15, 1907, the Lavagnino decision was discussed at some length. Prior to the Lavagnino decision, the law was generally understood to be that a re-location on lands actually covered at the time by another valid subsisting location is void. Such lands are not open to location until they have been abandoned or forfeited. It was generally conceded that the Lavagnino case held, in contravention of the then well settled law on the subject, that the forfeiture or abandonment of a senior location would inure to the benefit of a junior claim that was located so as to include a portion of the existing senior location. Many courts refused to follow the rule laid down in the Lavagnino case, either limiting the application of the rule, or contending that the more recent case of Brown v. Gurney, (210 U. S., 184), silently overruled the former case. The Supreme Court of Nevada, in the case of Nash v. MeNamara, (93 Pac., 406), refused to be bound by the broad rule laid down in the Lavagnino case, and after an exhaustive review of the authorities, held that the decisions opposed to that doctrine were too numerous to permit of "a result so revolutionary."

Now comes the Farrell v. Lockhart decision above referred to, written by Justice White, who also wrote the Lavagnino opinion, and clears up the atmosphere. The facts of this case are as follows:

The South-Mountain lode mining claim was located in August 1900. On August 1, 1901, and before the South-Mountain claim would have been forfeited by failure to perform the required annual labor, other parties located the Cliff claim, which was practically co-extensive with the South-Mountain ground. The South-Mountain owners failed to do their assessment work and, on January 2, 1903, the Divide location was made by still a third party and covered substantially the same ground. The Supreme Court of Utah (86 Pac., 1077) held that the Divide locator was entitled to the ground inasmuch as the ground was not open to location when it was included in the Cliff location, by reason of the existence of the South-Mountain location.

The United States Supreme Court, in commenting on the Lavagnino v. Uhlig opinion, says:

'... whatever may be the inherent cogency of that reasoning, in view of the experience of the courts referred to concerning the practice which it was declared had prevailed, in reliance upon what was deemed to be the result of previous decisions of this court, and the effect on vested rights which it was said would arise from a change of such practice and taking into view the prior decisions referred to, especially Belk v. Meagher, (104 U. S., 279), and also the more recent case of Brown v. Gurney, (201 U. S., 184), we think the opinion in the Lavagnino case should be qualified so as not to exclude the right of a subsequent locator on an adverse claim to test the lawfulness of a prior location of the same mining ground upon the contention that, at the time such prior location was made, the ground embraced therein was covered by a valid and subsisting mining claim..."

It is fortunate that the law on this subject is again settled and the Lavagnino doctrine relegated to history. A prospector who invades the boundaries of a prior, valid, and subsisting claim, acquires no rights whatever—present, potential, or eventual. If he wishes to re-locate ground, he must wait until the prior locator abandons it or is clearly in default in the performance of the work required by law to be done.

Bennett H. Brough.

FROM LONDON we learn of the death of Bennett H. Brough, secretary of the Iron and Steel Institute. As the author of a standard text-book on mine surveying he was known to students all over the world, and as a kindly, capable, and honorable man he will be regretted by members of his profession on both sides of the Atlantic. He was a graduate from the Royal School of Mines, where he served as instructor for seven years. As juror at several international expositions he did conscientious service. He also wrote many technical papers of more than usual interest. But all these are secondary to the actual character of the man and his influence for good as an individual. Many a man in the desert, in the jungle, and in the mountains, where mining is being done, will find his day overcast when he hears that Bennett Brough has crossed the range.
Personals.
S. F. Emmos is at Salt Lake.
Cesar Carant is in Arizona.
Arthur S. Dwight is at Saltida, Colorado.
Ferne S. Stewart is at Georgetown, California.
H. Kliarun Scott is examining mines in Greece.
Ugo Hesse has returned from Alaska, to Seattle.
C. F. Nourse has returned from Russia to San Francisco.
Hiram W. Hixon has returned to Philadelphia, from Ontario, Canada.
Richard A. Parker has moved his office to 404 Colorado Bldg., Denver.
W. D. Pearce is manager for the Hill Syndicate, in Las Vegas, Nevada.
C. Henry Thompson has returned to Los Angeles, from Durango, Mexico.
Arnold Becker was in San Francisco this week; he is now in Kern county.
Henry F. Lewis has been examining some properties near Murry, Idaho.
Douglas Waterman has been examining dredging ground in northern California.
Walker Fitch has resigned as superintendent of the Calumet & Hecla mine.
Owen Cummings has opened an office as consulting engineer at Redding, California.
Robert Stevenson, of New York, has completed a careful investigation of the Rawhide district, Nevada.
S. L. Sreak recently made an important report on the Great Boulder Perseverance mine, at Kellogg.
Howard T. Walsh, Pacific Coast manager for the Sullivan Machinery Co., returned this week from Chicago.
Estevan Ritter has been appointed consulting engineer to the Burleigh Mining Co., of Silver Plume, Colorado.
Waldemar Lenzien has accepted an invitation to lecture on geology at the Massachusetts Institute of Technology, Boston.
Forbes Richardson has completed an examination of the Saratoga mine, in Gilpin county, and has now left for Cripple Creek, Colorado.
W. Fleet Robertson, Provincial Mineralogist for British Columbia, has returned to Victoria from the new placer district on the Flathead river.
John Herman, formerly with the Cananea Consolidated Copper Co. in Sonora, has opened an assay office and chemical laboratory at Los Angeles.
C. E. Finn and E. W. Brooks, president and consulting engineer, respectively, of the London-Arizona Copper Co., have returned to Los Angeles from Koklin, Arizona.
Lester W. Stazaus has been examining coal lands near the Groya-Huancayo railroad, Peru. He will proceed to Huancavelica to examine similar deposits at that place.
S. E. Breasthorn has returned from Los Angeles, where he was engaged in the investigation of an important new wet process for the extraction of copper and zinc from sulphide ore.

W. C. West, formerly superintendent for the La Republica Mining Co., now holds a similar position with the Dawson Mining Co., of Sonora, Mexico, where he is erecting a cyanide plant.
W. S. Krost left Seattle on October 11 for Cooke City, Montana, to there erect a 200-ton smelting plant for the New World Power & Reduction Co., for which he will be general manager.

Dividends.
On October 1 the Pinguiclo Mines Co., Guanajuato, Mexico, paid its first semi-annual dividend on preferred stock, of $40,000, which is at the rate of three per cent.

General Mining News.

ARIZONA.

MOHAVE COUNTY.

The mill of the Gold Road Mines Co. is now closed down and will be replaced by a larger one. The work in the mine continues and is centered on driving toward the Billy Bryan vein from the 500-ft. level of the Gold Road shaft.

The rate on distillate, which formerly was $2.2 per ton, has been reduced to $1.7 from all California points to Kingman and Chloride, by a recent ruling of the Interstate Commerce Commission. The new rate goes into effect November 1. It is reported that J. W. Devity, who recently took a bond on the Abe Lincoln mine from Buchanan & Chittenden, is soon to arrive at Goldfield and will begin work on a 200-ft. shaft on the property. In the old shaft it is understood that an orebody averaging $17 gold was opened up. It is reported that work is to start at once at the Nighthawk mine, and that the affairs of the Company have all been straightened out. Dan Hanley and passes half a mile east of camp and it is the intention to operate all the machinery at the mine by electric power as soon as the power company is ready to deliver its current to mining concerns. J. B. Cleveland is manager.

YUMA COUNTY.

The Clarion Co. G. & C. M. Co., operating near House, has put another gasoline hoist in operation during the past month and has also purchased a water-jacket blast furnace of 200 tons capacity and the iron work for a 75-ton rever- sory furnace. A drift on the October 20 modifying the 200-ft. level has been driven 70 ft. and is still in an oxidized zone carrying native copper. A cross-cut on the 200-ft. level uncovered copper sulphides and has been driven 90 ft. across the orebody with the breast still in ore. George Mitchell is president.

The Cobralia Copper Co. is preparing to start active development at its property in the Ellsworth district nine miles northwest of Salome near Tank pass. Copper glance which carries $15 gold and 15 oz. silver in addition to the 1% copper has been found. Dick Hall is manager.

CALIFORNIA.

BUTTE COUNTY.

Increased activity is reported from Magalia ridge and the opening of the Cape Horn mine is sure to bring in an era of greater prosperity. In addition, the Mammoth and Guan channels are to be diligently prospected. Cohen & Gooday, of Magalia, are starting work and expect to drive a 600-ft. incline shaft to explore for gravel. In the Messilla valley the Blue Valley Co. is making extensive preparations for active work. This Company has been amply financed by Eastern capitalists. An order was entered in the U.S. Circuit Court, at San Francisco, to prevent the injunction of the Supreme Court of Butte county in the case of the City of Oroville vs. the Indiana Gold Dredging Co. The order permits the defendants to continue dredging in the channel of Feather river on the condition that a 50-ft. cut be made, within 15 days, through the transverse ridge of tailing now across the channel. The order allows the Indiana company to continue depositing its tailing in elongation of the ridge which runs parallel with Feather river, but it cannot erect or maintain a ridge extending above the present level of the ground upon which the dredge may be working.

NEVADA COUNTY.

(Special Correspondence). A heavy rainstorm prevailing for two days with excellent indications for a continued downpour, has solved the water question for a considerable period, and the various mines are making preparations for the resumption of activities. The tailings to the Empire mill are being rushed and the mine will be in full blast within two weeks. The shaft at the Union Hill will be sent down 650 ft. and cross-cuts driven from the 600-ft. level to cut the vein developed at the 300-ft. point. Ultimately the shaft will be sunk to the 1000-ft. level. The shaft has been enlarged to a three-compartment to a depth of 350 ft. A new compressor and concentrators have been purchased for the Central Com. mine and will be installed at once. A small force of men are employed and considerable milling ore has been blocked out. C. N. Bailey is manager. Morgan & Richards, of Nevada City, have placed a crew of men at work on the Alma mine, at Deadman's Flat, sinking the shaft and driving on a small vein of rich quartz. Arrangements have been made for the erection of a stamp mill at the Brandy City mines. The St. Gothard Mining Co., operating the Delhi mine, has declared a dividend of 5c. per share, the third for the present year. It is expected that work will be resumed at the Gold Flat in a few days.

Grass Valley, October 19.

SIERRA COUNTY.

Robert Duree has formed a company to work the old Gardiner vein near Poker Flat. The property was made to pay some years ago when a small stamp mill, the invention of Robert Forbes, was used. It is reported that a company represented by F. Heides has purchased the Cox property, below Howland Flat, and plans to put in some
THEY COUNTY.

The La Grange mine will start operations again as soon as a few minor repairs on the ditch are complete. R. Hesselwood has been prospecting the McCampbell gravel mines, at Hay Park, and will probably operate this year if the results are favorable. Sixty tons of ore recently shipped from the property on the Tom Greene road that is under lease to French Gulch men brought returns of $166 per ton. W. V. Whipple, who is manager of the Trinity Gold & Timber Co., of Minersville, has recently returned from Minneapolis, where he arranged for the purchase of a large amount of new machinery to be used in the mines of the Company. Last season's work is said to have been very profitable and consequently operations are to be conducted on a larger scale henceforth.

TIDALUMNE COUNTY.

Work has been resumed at the Excelsior mine and the new pump handles the large flow of water satisfactorily.

Charles A. Mac, of Los Angeles, has taken a bond on the quartz mines near Jacksonville, belonging to Mrs. M. A. Jones. A new company has begun the development of a promising property west of the famous O'Hara mine at Brown's Flat. The claim is called the Alta-Sonora and it is reported that prospects for gold are good. It is possible that a company of Nevada capitalists may re-open the Bonanza mine.

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence.)—Work was resumed this week upon the Joeson mine on Keil's Mt. The adit, now about 1100 ft., is to be driven ahead, while stoping will be started 1000 ft. from the portal of the bore. This property has just passed over to a company composed of Denver and Eastern men, Frank Babcock, of Silver Plume, having been appointed manager. The Waldorf Metals Co., leasing on the Paymaster, Commonwealth, and Central Indiana veins of the Wiijoc adit, as well as the Wheelieg vein of the Totten adit workings, has completed the full swing of the force is being added to from week to week and from now on regular shipments will be maintained. The product is to be sent to the smelters in Denver. The output promises to be heavy up until the time the Argentine Central railroad will be compelled to close for traffic for the winter.

It is reported that work will shortly be resumed upon the Indian, Lennor, and Miami Mtns. This property at one time was a good producer of high and medium-grade ore, but has been idle for a number of years. Another vein has just been cut by the Montgomery-Ward adit on Republican Mtn. On the foot-wall a streak of heavy lead ore is showing that is from 4 to 6 in. wide. No driving will be started until the hanging wall is reached. W. C. Hood is mining the Black Eagle, which he has developed into the 'biggest little mine' in the county is known as the G. & E. Eagle, situated in Highland Park, on the opposite side of the mountain from Georgetown. In the drift west of the sixt level a body of ore is exposed that is 6 ft. wide, the assays of which vary from $5 to $25 per ton in gold. On the fourth level the streak is from 2 to 4 ft. wide, the content being from $5 to $15 in gold. A peculiar coincidence in connection with this mound is that the ore mined on the Georgetown side has invariably been a silver product, while on the opposite it is always gold which has been found. The Black Eagle is operated by the Honest John M. M. & T. Co., J. F. Puchert, of Idaho Springs, being manager. A 40-ton concentrating mill is in continuous operation, an aerial tramway being used for the transportation of the ore. The Raymond adit cut another vein during the week, considerable scattered ore being in evidence. The bore has passed the 1000-ft. point, but driving will be continued. Work on the Rover, Griffith Mtn., is bringing results. In the breast of the adit a streak of heavy lead ore is showing that is 8 in. in. In the Bonanza there were three adits being cut, but no solid streak has yet been found. The Steeple adit will reach the objective within the next 30 days. Work will at that time be started in making the raise to connect with the Sunburst adit. The re-timbering, enlarging, and reducing of the grade in the adit has been completed and everything is in readiness for enlarged operations. S. McKirahan is superintendent. The Jackson adit is proposed to be enlarged, and in the meantime the new machinery is being run on Sun and Moon ore, made a clean-up a few days ago, and the machinery has been started on a 200-ton run of Rumsel Gulch ore for J. G. Roberts. P. Roberts & Co., leasing on the twelfth level of the Gem, sent out a carload shipment of smelting ore last week and received a settlement of $25 per ton net in gold. The streak measures from 4 to 5 ft. thick at the Twenty-Four. Mr. C. M. McLean, of Boulder County, a man of wide experience, will be put in charge of the news house adit, the initial capacity to be 100 tons per day. G. K. Kimball, of Idaho Springs, who is manager, departed last week for Pittsburg, to consult with the directors in regard to the construction of the plant. The Old Town has been for a number of years one of the heaviest producers of the district, and previous to the driving of the Hot Time lateral from the Newhouse adit, regular monthly dividends of 2½% were paid. A big body of medium grade ore has been found on the Silver Horn, at a distance of 700 ft. from the portal. The discovery was made in running a cross-cut to prospect the haunching wall. Assays of the streak show $16 per ton. The ore is ideally adapted to concentration. L. McLean, of Idaho Springs, is owner. Work is to be resumed in a few days on the Marshall-Russell adit, Coyote Mtns., after a close-down of five weeks. Georgetown, October 17.

GILPIN COUNTY.

Work has been resumed at the Illinois mine in Twelve Mile district in which a company of Denver men are interested. George Holland is in charge. There is some talk of the Rochester people installing a larger plant of machinery on that property in the Pine Creek district, and of resuming active operations again. Lumber is now being hauled up to the Wiedemann property at the head of Jenny Lind gulch to be used in building a shaft-house for the Union City M. & M. Co., in which Indiana people are interested, and in the meantime developments will be continued in the mine. The management of the Smuggler mine, in Moon gulch, has purchased an engine, boiler, and compressor and are considering the addition of five stamps to the existing mill. Grading was commenced last week on the extension of the lines of the Gilpin Tramway Co. in Willis gulch to the Anchor mine of the Heanne Gold & Copper Co., and is shaping up fast. Work is being continued on the mine and with the completion of the tramway Manager Kane figures that he will be able to ship in the neighborhood of 50 tons per day. The Sherman & Macain Mining Co. is to let a contract for 200 additional feet on its 950-ft. adit on Silver creek. Frank L. Branham is manager. A plant of machinery is being taken from the West Cahuon mine, at the head of Leavensworth gulch, to the Great Mammoth mine in Illinois Central district, The mine is owned by John Best & Co., and is to be worked by Gordon & Co. under a lease. Some ores are now being taken out of the main shaft with a winch arrangement. It is reported that work of driving the adit of the Black Hills & Denver Mining Co., on the north side of Boulder Park is to be started again. Large ore bins have also been built at the head of the tramway leading to the mill and it is expected that
trial runs will soon be made at the Company mill on some of the ores.

SAN JOAN COUNTY.

Three shifts are at work at the Gold King mill, at Gladstone, and 40 stamps are dropping. The shipments of concentrates are averaging more than one car a day and have been estimated that the output for October will be more than 1000 tons. Several carloads of lumber have already been shipped from Silverton for the mill at the Bonanza, and the grading will be started within a week. The management hopes to have the plant running before snow flies next year.—The Silverton shipments for October amounted to 2200 tons of concentrate and 1500 tons of crude ore, which represents about 17,000 tons of ore mined.

SUMMIT COUNTY.

The new gold dredge, under construction on the Nembka ground by the French Gulch Dredging Co., is nearing completion and will be placed in commission this fall. This will make the fourth dredge in active operation in the Breckenridge district.—Work has started on the Wapiti group near Georgia pass.

TELLER COUNTY.

Henry Yohe, general manager of the Francesca M. & L. Co., will start active operation on the Roxanna property on the northwestern slope of Raven hill. The Company will put the block of ground on which it will operate and make the improvements immediately and as soon as machinery is put in will start active development work. Some time ago the Roxanna property was blocked out for leasing purposes and of the eight blocks, six are now in active operation by lessees.—Cripple Creek men have secured a lease on the Phoenix property of the Isabella Mines Co. and are now engaged in putting the property in shape to operate. A complete plant of mining machinery will be purchased and active work started.—J. K. Lewis, of Cripple Creek, who has a lease on the Bob Lee claim of the Bob Lee Co. Mining Co., has struck ore in a drift from the 100-ft. level, which assays $25 per ton gold. He will put up a new hoist and make a trial shipment at once.—The surface buildings of the Gold Sovereign mine, at Cripple Creek, were destroyed by fire, on the night of October 15, believed to have been of incendiarY origin. The loss is estimated at $30,000.

IDAHO.

IDAHO COUNTY.

(Special Correspondence.)—W. S. Smith, of San Francisco, has been examining the Cleveland group of claims, in which he is interested, and stated on leaving the district that electric pumps would be put in operation next winter, and that the property is about eight miles from Elk City. —John Massam and associates have bonded their group of four quartz gold claims near Elk City to J. R. Painter, of Wyoming, for $60,000. Work will be begun at once on the driving of two adits to tap the ore at about 100 or 150 ft. Cabins are now being built. A water power capable of running 10 stamps is also under Mr. Painter's control, and he expects to erect a small mill next summer. Mr. Painter also bonded the placer workings of Joseph Alken, which have yielded a small amount of gold, but have not been extensively developed. The gravel is loose and there is an abundance of water for giants.—George Stonebreaker, who owns the Buckhorn group of quartz claims on Crooked river, has stopped operations for the winter. He reports having made a satisfactory clean-up late in the season with an arraste, but that this method recovers but little of the gold, and will be replaced by a small modern mill next spring.

Elk City, October 17.

SHOSHONE COUNTY.

(Special Correspondence.)—The Murray Development Co. has been organized, composed chiefly of Boston capitalists, for the purpose of developing and controlling the Mober Lode group of 11 placer claims. The consideration has not been made public, but it is understood that the amount involved is large. The property is equipped with a 10-stamp mill and more than $1,000,000 worth of gold has already been taken from the ground. As soon as all the necessary details have been completed it is the intention of the Company to work both the mine and mill to full capacity.—E. M. Smith has sold the control of the Golden Winnie Tungsten M. & M. Co. to Arthur Anon, of Kennewick, Wash., and associates. The cash consideration was in the neighborhood of $75,000, but Mr. Smith still retains a large interest in the mine and will occupy the position of manager. It is the intention of the new management to install a concentrator especially designed for this treatment at the tungsten ore. The ore shoot has been opened up for major hundreds of feet, and the assays show that the gold content alone will be more than sufficient to meet all transportation and treatment expenses. The mine is advantageously situated on the line of the Idaho Northern railroad.—A movement is afoot for the driving of a big 1000-ft. adit, on a co-operative plan, for the development of a number of the Murray mines. This adit can be driven practically from the tracks of the Idaho Northern railroad and will tap at great depth the ore-shoots of the Bear Top, Chicago-London, Black Horse, Paragon, the Jewett group, and the Orofino properties, all of which are ready to commence shipments as soon as the Idaho-Northern railroad reaches that point. The cost of this project is estimated at $75,000, but those who are promoting the scheme claim that the value of the blind shoots out of this ground is more than sufficient to make the investment. The portal of the adit is an extensive mill-site, and it is possible that a large capacity concentrator will be erected for the treatment of the ores.—Work in the face of the lower adit of the Chicago-London Co. has been commenced again this week with a force of ten men. The work is handicapped for want of power owing to the shortage of water. With the recent rains, however, it is believed that the Company will soon be able to start up the 15-drift compressor, owned jointly with the Paragon Co., and to increase the force at work. The largest orebody in this mine has already been opened up for a distance of more than 500 ft., and is several feet wide almost all the way. This vein has been traced on the surface for over 2000 ft., and it is the intention of the Company, as soon as the railroad has guaranteed reasonable transportation facilities, to erect a 150-ton concentrator especially adapted for the treatment of zinc ores.—Work on the property of the Corrigan mine is about to be resumed by the Federal Mining & Smelting Co. This property has been closed down ever since the recent depression on the metal market, but it has now been announced that extensive improvements are contemplated. A 20-drift compressor and motor have been ordered, and the equipment is expected to be ready as soon as this machinery has been installed a force of between 60 and 70 men will be employed.—Herman J. Ross j, of Wallace, has just completed a transaction by which he has secured the one-sixth interest in the Amazon-Dixie mine, in the Saltse district, owned by Mark Everett. The consideration was $20,000. Very little development has been done on the property, but one of the best showings in the district has been made. A large amount of equipment has been installed and already a deal has been consummated for the sale of 100,000 shares in the new organization at a high figure.—Shipments of ore from the Butte & Coeur d'Alene property will commence as soon as the Company has finished the wagon-road at present under construction. This decision was reached at a recent meeting of the directors. The property is located in the Badger mine and the Snowstorm mines in the Mullan district, and last week a strike of three feet of ore averaging about 11% copper, 7% lead, and 300 oz. silver was made in the face of the drift on the vein from the end of the 500-ft. adit. This ore has already been proved to a distance of about 100 ft. and one car is now ready for shipment.—Still another suit has been commenced by the Federal Mining & Smelting Co. against the Bunker Hill & Sullivan Co. This suit is of the nature of an adverse claim, in which the Nellie property, owned by the Federal, is said to conflict with the Cheyenne claim owned by the Bunker Hill & Sullivan.

Wallace, October 17.
At The Clarke the depth is $149,360.

The mining companies would not add the Cardinal in pumping, and it found it impossible to keep the water from so large an area. The mill was moved away and the mine remained inactive until the present company began working this summer. The ores will be cleaned upon hand-jigs.—The Florence Mining Co., near the above leases, has struck a rich run of galena at 40 ft. The ore occurs in large chunks weighing as high as 50 to 100 lb. This is the fourth strike upon the land within the past year. Two distinct runs are being worked, both rich in galena and zinc-blende. The region southeast of Joplín is also active. The old Carnegie-Galena mine has been sold to the Grace Holmes Co., but the consideration has not been made public. This is one of the old producers, having turned out 1,000 lb. of ore on one of the company's leases. This ore came from the shallow levels at 120 ft., but recently ore has been found by drilling at 160 to 210 ft. Hand-jigs will still be used by the new company, but when the lower levels are worked a new mill will be constructed, and thus secure a 50% reduction in royalty. Work will begin by the last of October. —A shallow lead strike has been made on the Wilkes land southeast of Joplín which has caused a considerable stimulation of activity on adjoining leases. The ore was struck at 30 ft., and is of exceptional richness. It appears to rival the rich strike made in the Leadville Hollow camp a few weeks ago. The ore is in almost pure chunks and requires no crushing or jiggling. It is ready for the market when the mud and clay are washed off. Neighboring leases have been snatched up and a number of shafts are going down rapidly in hopes of striking the same vein. Another company has just under the management of Harry Kingsbury has taken over the lease worked by A. P. Clarke and associates and has installed a large centrifugal pump in the shaft, which is 140 ft. deep and in good ore. The former company gave up the work on account of excess water. A high-grade zinc-blende, resembling the grade found in the well known Bumble Bee mine, is found there. The mine is in the southwest corner of the famous Thousand Acre tract. —Another find of great importance was made in the Alladin mine at Spring City. While running a drift from No. 6 shaft, just above the 100- ft. level, a run of zinc-blende was uncovered. It is of the "robin's jack" variety and is as nearly pure as any ever found in the district. A new shaft is being sunk at the mill which will be used to open the new orebody and the No. 6 shaft will be abandoned. Another run of zinc-blende has been opened in the Hallowe'en mine, where a new shaft has just been sunk to the ore level, which is at 100 ft. Driving will be started at once and a 100-ton mill erected before winter. The Hallowe'en is on the crest of the hill, while most of the other mines in this camp are in the valley. —Plans are under way for the re-opening of a number of plants which have been idle for some time in the past, one of which is the Bumble Bee, southeast of Joplín. Pumping machinery has been installed and as soon as the mine is drained workmen will be put into the drifts. A shaft is being sunk during the draining of the ground. The water problem is serious, as the drifts are large and numerous, and many idle mines in the vicinity are filled with water. It will be necessary to have the Bumble Bee pumps. —The large galvanized plant of the United Zinc Co., at Duenweg, will be re-opened as soon as the ground is drained. This mill was now last year and has been run long, as operations were suspended when the panic came. The property is well developed with two shafts to the ore-level, where a rich sheet run of zinc-blende has been opened. The plant is one of 600 tons and one of the best in this part of the district.—The Endeavor mill, recently completed on the Prudential lease, is now operating upon a rich galena and zinc-blende run at 216 ft. The ore is turning more than 95% galena and zinc-blende. There is a 2 ft. face of galena at the top and also the same at the bottom of the run. A new shaft is being sunk near the mill, while the ore at present is being hoisted from an old shaft, and being trammed a long distance to the mill.

Joplin, October 17.

NEVADA.
EMERALDA COUNTY.
A station is being cut at a depth of 630 ft. on the Jumbo, one of the Goldfield Consolidated properties, to connect with the main shaft of the Mohawk, which is down 600 ft. When this is done the work of sinking to cut the main Mohawk vein and ore shoot will be continued. —The Goldfield CI mill, at Goldfield, has been completed and began operation last week. It uses what is known as the Greenwalt Electro-Chlorination process. The leaching solution is generated from sodium chloride by means of an electric current, and the precipitation of the dissolved metals is also aided by electrolytic action. This process is claimed to be effective for the extraction of both gold and silver.

—The Zian-Florence is installing air-drills, preparatory to starting prospecting the Jumbo Florence dike. For the present the power will be obtained from the adjoining Florence Consolidated lease. —A five-drill compressor and a 50 hp. electric hoist were installed last week on the Florence Consolidated by M. T. Kieley, who has completed the installation of a 100-hp. hoist on the Goldfield Florence.

—Two shifts are rushing work on the 315-ft. level of the Gotwaldt lease, under direction of T. D. Van Devort and J. H. Grant. Driving is progressing in both directions, the hanging wall having been reached last week. —At a depth of 614 ft. a station was cut last week in the Claremont shaft, which will be one of the principal working shafts of the Goldfield Co. A cross-cut is being run to connect the Claremont with the Mohawk.—The Rockland Syndicate Mining Co., owning the famous Rockland mine, near Mason Valley, is making preparations for the installation of a modern reduction plant for the treatment of its ores. This mine has been developed to a depth of 1000 ft., and has blocked out in and out, according to the reports of competent engineers, 70,000 tons of milling ore that will average 10% per ton. The Rawhide Western, in connection with the St. Ives Leasing Co., for both of which A. A. Codd is president, announce that they will build a 10-stamp mill at Modoc, the junction of the Southern Pacific and the Rawhide Western, six miles below Schurz. The first unit will have a capacity of 50 tons per day and construction will be started as soon as the Rawhide Western railroad is completed. —The mines of Goldfield produced during the ending October 17 a total of 1896 tons, of an estimated value of $149,500. During the same period the Tonopah mines produced a total of 5125 tons estimated to be worth $131,700.

NYE COUNTY.
During the past week the east drift from the No. 2 shaft of the West End Co., at Tonopah, has made connection with the west drift from No. 1 shaft on the 400-ft. level, and work from now on will be for some time on the main shaft. The old ore house near No. 1 shaft has been torn down, and the new bins, which are nearly completed, will be used for the sorting and loading of all ore from the mine. —The work of sinking the Stone Cabin shaft, of the Jim Butler, to the 700-ft. level was completed last week, the bottom being down 707 ft. This will give the Company an additional depth of 500 ft. over the old workings, and prospecting from the bottom of the shaft will be started as soon as the station has been cut.
tions are still confined to the different levels from the Silver Cabin shaft, no work being done there by Wandering Boy. The ore shipments last week consisted of 240 tons to the Belmont mill at Millers.—The old Jefferson mine, now known as the Charles Konrath, near Round Mt., has been purchased by Charles Brennenman, J. Flick, and W. H. McBeath, of New York, for the sum of $356,000. The new owners expect to sign a contract at once for the erection of a $15,000 milling plant. The mill has already been selected, and the order for shipment has been awaiting the closing of the contract for the purchase of the mine. The plant will have a capacity of 200 tons per day, and will be in operation, it is thought, by the first of January.—The Taylor Bullfrog Mining Co. is again working its property near Beauty.

OKLAHOMA.
OTTAWA COUNTY.

(Special Correspondence.)—The Miami camp still holds its own with the older camps of the district. The most important item of news is the discovery of a rich vein on the lease of J. W. Barnes. Seven drill-holes showed the deposit occurring at 144 ft., and continuing to 165 ft., the whole 19 ft. averaging over 20% zinc-blende. Another development of deep ore was made by P. C. Campbell near Tar creek. The development of deep ore is an important one, as it not only assures a longer life to the camp, but the ore found at the lower level is of a much higher grade than is found at the shallow levels, where the mines in the camp have been taking the ore.—The Miami-Yankee Co. has purchased the old McCord mill, in the Joplin district, and has moved it to the lease in the Miami camp. The mill has been run only a short time, but it will be improved and adapted to the ore in the Miami camp. The Company has been studying the different mills with a view to installing the best features in its new plant, as so much so far has proven entirely satisfactory in handling the Miami ore. Besides this mill three other plants are being erected in the camp, namely, the Muskogee, Golden Hien, and Dan Isley. Considerable development work has been done in each mine preparatory to the erection of a mill. Seven plants are already operating.—A strike was made on the shaft 69 ft. deep and 100 ft. west of the shaft 29 ft. deep and 90 ft. west of the earlier strike. One of the latest drill-strikes of the camp was made on the beds of the Washillus. It also has under consideration the erection of a 200-ton mill.

Miami, October 17.

WASHINGTON.
STEVEN'S COUNTY.

(Special Correspondence.)—Owners of mines in the Meta-line district have interested several local capitalists in the building of an electric railway from Metaline to North-port, a distance of 20 miles, to haul out the ores that are now beginning to be produced there. The camp has been under development for three years, and contains valuable and extensive lead deposits, yet its isolated situation has entirely prevented its being worked profitably. Several plans for getting out the ores have been attempted, but so far have failed. The Washillus, on the Pend d'Oreille river, has until within a few weeks prevented steamers from reaching the district, thus making it necessary to haul supplies and such ore as was desired for testing, a distance of 12 miles up-hill to a safe landing. The railway is still 60 miles away, while egress westward across the mountains to the S. F. & N. railway is out of the question. Roads have been cut, only to prove failures so far as the ore was concerned. Recently a steamer has been built for the Box canyon run, that can take the ores out to the south, where they can be distributed over the Great Northern and the Northern Pacific systems to the smelters. The present plan, however, far surpasses all those yet proposed. A suitable grade has been roughly surveyed to Northport, and the distance lies last 50 miles and there is abundant water-power for generating electricity, an electric line seems to be a feasible outlet. It is stated by those interested that $200,000 has been virtually promised, contingent upon final agreement of the Northport smelter people to install a lead stack. This has been promised informally, and it is now believed that the matter is accomplished. If nothing happens to prevent, work will by commenced this fall, and by early spring, it is said, the road can be in operation. It will be a boon to several properties worthy of attention. As further evidence of the growing importance of the district, R. A. Blackwell, general manager for the Idaho & Washington Northern railway, announced a few days ago that his line will be extended next summer to Ions, which is but 12 miles from Metaline, and that a survey is now being run through to the camp. This will at once afford competing rates on treatment and transportation by rail, and will doubtless cause an expansion of the mining industry at Metaline.

Metaline, October 17.

CANADA.
BRITISH COLUMBIA.

The Hidden Creek Copper Co., of Seattle, has recently made the final payment of $30,906 on a $100,000 option on the property lately acquired from J. Mills and others of Vancouver. The mine is at Goose bay, about 100 miles from Prince Rupert. A compressor, pipe line, and machinery is being put in and development carried on.—The Dominion Copper Co. has commenced the erection of a new machine at the smelter to replace the one destroyed by fire some weeks ago. Orders have been placed for new machinery to equip it.—The Granby company will shortly install a new electric mill, and will put a powder thaw, replacing steam by electricity. Air will be heated by means of electric cells and blown by a fan into the thaw. If the new system operates satisfactorily a similar one will be put in at the Gold Drop. —The mines of the Dominion Copper Co. have been closed pending a re-organization of the company. The low metal prices, the recent fuel troubles, and payments of interest soon to be met, will, it is said, result in the appointment of a receiver. The physical property of the company is in good shape and with the advancing metal market and a re-organization of the concern, the present shut-down should not last long.—Tenders for the construction of 300 miles more of the Grand Trunk Pacific Railway in British Columbia will be called for within the next month. The contract is for 300 miles with the best line between Wolf river, and 100 miles eastward from the end of the 160 miles already being constructed along the Skeena.

ONTARIO.

Peter King, an American prospector, reports that he has found very rich ore in the Sturgeon Lake district, where he has been prospecting since early summer. He has much rich ore to base upon his statements and shows some nuggets weighing over an ounce each. It is the richest gold find ever made in that part of Canada or in the whole Dominion, even eclipsing the rich mine near Wabigoon owned and operated by Anthony Blum of Boston. King has refused several large offers for the property.

YUKON TERRITORY.

The big ditch of the Yukon Gold Co. from the head of the Twelve Mile river to Bonanza creek, a distance of 76 miles, is practically completed. It was originally intended to turn the water in this season, but it has now been decided to wait until next spring. The work has been continuous during the past three seasons and involves a total expenditure of approximately $3,500,000. Two thousand men have been employed, two-thirds of which have been working on the plant. The ditch is wide enough in places for three teams to drive abreast, and will carry 20,000 inches of water. The pipe line varies from 46 to 49 in. and has a capacity of 5000 inches. The engineers in charge are O. B. Perry and Chester A. Thomas.
Special Correspondence.

NEW YORK.
Greene Gold-Silver Co.—W. B. Thompson on Copper.—Quicksilver Production.—Mining Stock Market.

The Greene Gold-Silver Co. appears to be in a bad way. Some months ago a committee of stockholders, including two directors, was formed to investigate thoroughly the physical and financial conditions of the Company, but as less than $10,000 was raised of the $25,000 necessary to pay the expenses of the investigation was abandoned, and there is little hope of the Company giving any return to the stockholders on their investment. Organized as a Mexican corporation, the Greene Gold Silver Co., S. A., owns title to all the properties, and the West Virginia Co., the stock of which is widely scattered, has as its only asset the stock in the Mexican company. According to the statement of a director this Mexican stock has been hypothecated, and the American company loses its assets, as it is said that the properties are to be sold at auction shortly to satisfy the loans of the Mexican banks. This marks the last stage of a fine example of how not to finance mines.

Regarding the future of copper, W. B. Thompson is quoted as follows: “I am looking for a temporarily uncertain stock market because of political conditions, but my report is the same that there is assurance that the election of Taft is assured and the market should begin to discount that fact about two weeks before election. As to copper, it is apparent that the European market is pretty well sold up. Not only the manufacturers, but the speculators as well, have loaded up with cheap copper, so that we cannot expect much help from the other side in assimilating our production. At the moment it is evident that we are producing more copper than we are consuming, but as there is still a considerable amount to go to the other side, and the American consumption is increasing, it may be a month before copper begins to accumulate in this country. The producers of copper appreciate the situation, and are prepared to carry their copper until the resumption of business late this year or early next year, when the price of copper is bound to advance. I am not so sure but that the consumers, appreciating this situation, will begin to stock up in anticipation of future needs, in which case we may get higher priced copper immediately after election.”

An interesting comparison is made between the mining camps of Butte, Montana, and Cobalt, Ontario. Each of these camps is expected to show net profits this year of about $1,900,000. Butte will get this from the production of 15,000,000 oz. of silver from 20,000 tons of ore, while Cobalt will have to treat 4,000,000 tons of ore to obtain the net returns in copper and silver.

The total production of quicksilver in the United States for the current year will probably be about 17,000 flasks, which will be the smallest for many years. The production since 1904 has been as follows: 1904, 22,000 flasks; 1905, 19,000; 1906, 22,000; 1907, 18,000; 1908, 17,000.

The steady decline is due to the gradual exhaustion of the orebodies, and while 5 years ago there were 20 mines in the country producing quicksilver there are now only 10. The mercury mines owned in Boston now produce 75% of the entire United States output; the New Idria quicksilver Mining Co. yields 800 flasks per month, or 9,600 per year, and the New Idria Navy Yard 2,400 flasks annually. The New Idria is producing more than ever before, credited to the work in high-grade ore with the largest reserves in its history. With the quarterly dividends declared last week the Company has paid out in 11 years $1,050,000, or $10.50 per share, more than twice the original subscription price of $5. Beginning with April the Company has increased its dividends from 20 to 30c. quarterly. The present price of quicksilver is $15 per flask as compared with $40 last year, and the demand absorbs the entire production.

The market for mining stock has somewhat improved. The general sentiment on the New York ‘curb’ is bullish, and brokers expect a season of prosperity for the mining industry after the election. This is based on the showing the mines have made during a year of depression; development and construction have been pushed, and output and dividends have been maintained better than was expected. While the majority of the actual sales of mining securities are not recorded on the curb, and the prices quoted there are not always representative of property, this institution is a valuable indicator of the feeling of the outside public with regard to mining securities. The Goldfield Consolidated stock has been a puzzle to some operators. It varies between $4.50 and $7, and large buying orders placed by outside interests to cause a market movement have failed to raise it above the latter figure, as the stock has been freely offered by those in control at any advance. It is suggested that the reason why the speculators are opposed to any big movement may be found in the history of Nipissing, which advanced from $9 to $33 per share in two days. The public bought heavily at high prices, and when the decline came investors lost their money the whole Cobalt camp was injured, and it has taken two years for it to recover its prestige. For this reason the Goldfield insiders may have determined to keep the stock within reasonable limits, and so retain public confidence and attract permanent investors rather than speculators. The new mill is now approaching completion, and if the tests in February are satisfactory a big rise is expected in stock, as its intrinsic value will then be much higher. The wisdom of the present course will be seen if the mill does not do as well as expected. Even in that case the stock is so well controlled that the decline might be small and the investors would continue to give support.

LONDON.
Sir George Livesey, Engineer and Economist.—Venture Corporation Re-organization.—Tungsten Production from Carnish Tomboy Gold Mines.

By the death of Sir George Livesey, this week, England lost a noteworthy example of the honest business man and able engineer. Though connected, not with mining, but with gas manufacture, he deserves a corner in your pages because of his methods of dealing with capital, profits, and labor. He was born in 1834, and when 14 years old entered the service of the South Metropolitan Gas Co., which has the monopoly of the supply of gas over practically the whole of the south of London. For 60 years he was connected with this Company. He joined the board of directors in 1852, and from 1883 until his death he was chairman. His qualifications were in no small degree due to the fact that he was a member of council of the Institution of Civil Engineers. One of the most noteworthy theories of Sir George was that dividends paid by monopolies or protected industries should be in the inverse ratio to the prices charged for the commodity supplied. That is, if the profits increased, the surplus should be devoted partly to the reduction in debt and partly in payment of dividends. In this way the monopoly is prevented from becoming bloated. Shareholders receive a fair return on their money and the public is served well. Economy and efficiency of administration become responsible for prosperity and success, and not the mere possession of the monopoly. Sir George was also a great supporter of the claims of the workmen, and devised many methods of making the men interested in the system, and working in high-grade ore with the largest reserves in its history. With the quarterly dividends declared last week the Company has paid out in 11 years $1,050,000, or $10.50 per share, more than twice the original subscription price of $5. Beginning with April the Company has increased its dividends from 20 to 30c. quarterly. The present price of quicksilver is $15 per flask as compared with $40 last year, and the demand absorbs the entire production.

The scheme then put forward offered such men as agreed not to strike or in any other way injure the company, an annual sum as bonus, calculated as a percentage of the wages and determined by the price of gas. The men would have the option of receiving the bonus in cash or of leaving it in the hands of the Company at 4% interest.
This was an honest proposal, but the trades unions resented it as an interference with the reason for their existence. After two months the men came to terms, and everything has worked smoothly and satisfactorily since. At the present time, the workmen own £50,000 worth of shares in the Company, and have three representatives on the board of directors. The low price of gas will be a wonder to Americans, for it is never higher than 60 cents per thousand cubic feet. There is an excellent pension fund for such as have been in regular employ. It was Sir George who first inaugurated the system of penny-in-the-slot gas cookers, which brought the gas fire within the means of the very poorest, and incidentally improved the air of London.

I wrote a few weeks ago of the Improvement in the position of the Venture Corporation, and mentioned that for the first time in eight years a balance sheet and report had been issued. The directors have since considered the advisability of reconstructing the Company and amalgamating with it the other companies that are more or less affiliated with it, namely, the London & Continental Investment Corporation and the Mines Corporation of New Zealand. Their scheme has now been circulated among shareholders. The new company is to be called the Venture Corporation 1908 Limited. The capital is to be £250,000, in 1,250,000 shares of 4 shillings each. For every 100 £1 shares in the old Company, 23 fully paid and 100 credited as 2s. paid will be allotted. For every 100 £1 shares in the London & Continental Investment Corporation 63 shares credited as fully paid and 23 paid will be allotted. For every 100 £1 shares in the Mines Corporation of New Zealand 9½ shares credited as fully paid and 12½ credited as 2s. paid will be allotted. If all the shareholders come into this scheme, 345,832 fully paid shares and 650,000 partly paid shares will be issued and £88,000 new working capital will be available. I believe a large proportion of the old shareholders will content themselves with the acceptance of the fully paid new shares, and will fail to take up the new shares that carry a liability. The directors are of the same opinion, for they have arranged for the underwriting of 400,000 of the partly paid shares. This new scheme will be placed before the shareholders at an early date.

An interesting development of the Cornish mineral industry is the formation of a new company called the Tungsten Metal Co., the object of which is to produce metallic tungsten and tungsten salts from Cornish ores. This Company has been floated by the Allen & Meyerstein group, which has done so much to develop Cornish mines, such as South Crofty. It is not quite correct to call the Company a new one, for it is really a reconstruction of the Tungsten & Rare Metals Co., which was run by Steinhart & Vogel in South London for a number of years. The old venture was started before the supplies of wolframite were made available by the introduction of the magnetic process for separating it from the tin with which it usually occurs. At the time the Company relied chiefly on Spain for its source of supply, and had a contract with the San Finix company. Partly owing to the difficulty of obtaining suitable supplies of ore in competition with the German producers, and partly because of the site of the factory, in South London, where the cost of carriage of raw materials, such as acid alkali and fuel, was a serious item, the Company was not a commercial success. Its reconstruction at the present moment is opportune. The new works are to be at Widnes, in Lancashire, in the centre of the coalfields and chemical industry, and the supplies of ore will come freely and on good terms from Cornwall. Mr. Vogel is to be manager, and Dr. Steinhart will act as consulting chemist. The consumption of tungsten in England at present in the manufacture of tool-steel and salts is about 1500 tons per year, and it all comes from Germany, some of it being smelted from Cornish ore. The use of tungsten for metallic filaments of incandescent lamps will provide a new market for the metal; at present these lamps are made in Switzerland, but, to comply with the requirements of the new British patent law, a factory will shortly be established in the midland counties. The Tungsten Metal Co. is a decidedly interesting venture, and should be strongly supported.

The Tomboy Gold Mines Co., which owns the Argentine group, at Telluride, Colorado, is now working in low-grade ore, but by a judicious mixture of the poorer quality from the lower levels with the better class from the upper workings, the successful operation of the mine will be continued for years to come, though the monthly profits will be reduced. For some time the profits have been about £2000 per month, but in future these are expected to be reduced to £1500. It is not proposed at present to develop...
farther in depth, but thoroughly to open the ground already partly developed. The reports issued by the Company do not give definite figures relating to the lower-grade ores now forming the bulk of the ore reserve, but presumably the recoverable reserve will be about $7 per ton, as compared with $10 hitherto. This, averaged with the better grade, would give about $8 for some years to come, and yield the £5000 profit per month indicated by the directors. [An abstract of the annual report of this Company, just issued, will be found on another page of this issue.—Edtor.] The ore reserves have been well maintained, and amounted practically to the same figure as a year ago, namely, 400,000 tons, but no estimate is given of their content, so their relative value can only be guessed. It is interesting to note that additional plant has been erected during the year for the object of treating the middlings produced in concentration. By means of additional classifiers, Whitney tables, roasting-furnaces, and magnetic separators, the copper and zinc products can be separated from the pyrite, and marketable products obtained. This plant was first put in operation in January, and has gradually been brought to a state of high efficiency.

**COBALT, ONTARIO.**

September Output.—Preparations for an Active Stock-Market.—Work in Outlying Districts.—Gold Excitement at Sturgeon Lake.

The output of the Cobalt mines for September, amounting to 3223 tons, is the largest for any month in the history of the camp. Hitherto the record month was November 1907, when the shipments were 2516 tons. The first place was held by the Nipissing mine with 607 tons. The Drummond shipped 541, and the La Rose 460. Shipments for October thus far have not been on so heavy a scale, those for the week ending October 10 amounting to 465 tons from the following mines: Cobalt Central, 20; Kerr Lake, 40; Nipissing mining Co., 140; Brien, 95; Temiskaming, 30; and Temiskaming & Hudson Bay, 90. Prices on the stock market have generally held firm, with occasional spurts due to favorable reports affecting particular mines, but there has been no great buying activity. A powerful factor in maintaining prices is the general expectation that as soon as the Presidential election is fairly over in the United States there will be a great demand from American investors, as a result of the recent visits made to the camp by many American financiers and mining men. This is anticipated whatever the result of the election may be, as in the somewhat unlikely event of Bryan’s election it is pointed out that Canadian investments would have special attractions as being beyond the range of American legislation unfavorable to capital. In expectation of an active market there have lately been new nominations of directors and reorganizations. The Otisse Mining Co. has been incorporated with $2,000,000 capital to develop the Otisse mine at Silver lake on the Montreal river, with Frank C. Loring as engineer in charge. There is a 2-ft. vein running across the property with silver extending for 6 or 8 in. into the wall-rock on either side, the metal content being estimated at from 5000 to 10,000 oz. per ton. A few days ago another find of native silver of large extent was made on the surface. A large force of men is at work. The Little Nipissing Co. has decided to increase its stock from $650,000 to $1,000,000 to obtain funds for the development of a 12-in. vein which runs under the lake, in working which it is expected to prove the value of other veins which may be found. A recent discovery at the Nancy Helen is proving rich in native silver and contains about 10,000 oz. silver per ton. The Company will open up this vein at three different points, driving each vein. The Beaver has opened into a streamer at the 200-ft. level, showing good silver content and supposed to be an offshoot from the big Temiskaming No. 2, which the Beaver has been working for some time favoring to reach the Trehether a calcite vein rich in silver has been found at 100 ft., at a distance of 1300 ft. northerly from the main workings, near the Hudson Bay boundary. The Warner property of 200 acres in Bucke township, where a massive cobalt vein was worked last winter, has been bought by a Chicago syndicate which organized the Agana Mines Development Co. There is a shaft on the property down 125 ft., and 175 ft. of driving has been done, but recently the plant was burned and work discontinued. Silver has been found at the bottom of the shaft and other silver-yielding veins have been traced. A new plant has been ordered and development will be pushed. New buildings are to be erected on the Cochranes property and the recently abandoned, and the shaft near the Temiskaming will be sunk to the 200-ft. level. A rich orbeody has been cut at the Nova Scotia at the 140-ft. level of the main shaft. The vein has widened from 6 in. to 2 ft. A concentration mill will be installed.

H. E. T. Haulain, a prominent mining engineer who has had experience in important positions in British Columbia, South Africa, and the Western states, has been appointed associate professor of mining in the faculty of Applied Science, Toronto University. Walter H. Aldridge, general manager of the Consolidated Mining & Smelting Co., was in Cobalt last week arranging for the shipment of low-grade ores for treatment at the Trail B. C. smelter. There is a rush of prospectors to the Sturgeon Lake, Algoma district, goldfields. Oldtimer, Peter King, who discovered gold in that area nine years ago, has recently returned from Sturgeon Lake to Port Arthur, with some very rich specimens. A number of locations are being taken up and a large amount of ore sacked for shipment. The ore is reported to be so rich that it can be sent direct to the smelter.

**MEXICO.**

Changes in Railroad Rates.—New Construction at Pachuca.—Development in Guerrero.—Mine Consolidation at Cananea.—Increased Activity in Chihuahua.—Re-organization of Alvarado Consolidated.

The Railroad Commission has not rendered a decision on the increased rates demanded on imported coal and coke. It has been shown that the domestic production for the last half of 1907 was 450,000 tons of coal and 60,000 tons of coke, whereas the consumption for the same time was 710,000 tons of coal and 240,000 tons of coke. If, then, the Mexican producers could increase their output 50%, which they claim to be able to do, it would just satisfy the consumers of coal, but would still leave a shortage of 150,000 tons of coke. To increase the railroad rates as asked, without discrimination, would be an unjust and unreasonable burden upon the consumer, and it is not believed the commission will allow the full increase as asked. It is probable, however, that some plan will be made to protect the home product at competitive prices, that is, from Monterey and Torreon north, and including possibly San Luis Potosi, but not Aguascalientes or Mexico City.

At the Real del Monte, in Hidalgo, where the successful treatment of Pachuca ores was first accomplished, enlargements have already been made. The Loreto mill is to be made a duplicate of the Guerrero. The new 300-ton mill of the San Rafael y Anexos has 40 stamps of 1000 lb. and 20 of 1200, dropping in weak solution; from these the pulp goes to classifiers and thence to three Krupp tube-mills, and through settlers to a Brown air agitator, where a stronger solution is introduced. From the Brown agitator the pulp goes to Moore filter-presses, which are in duplicate, having a capacity of 150 tons each. Though the dividends from the Company have been $1.50 per share, it is believed that the new mill will enable the Company to double these, and the stock, which is but 5000 par, and has been selling for the last year at about $1800 per share, has now mounted to $3400. For the Union mill has also been ordered a Moore filter-plant of 150-ton capacity, which in treatment will be exactly the same as the San Rafael. The ores being practically identical. At the Cla. Beneficiadora de Metales de Pachuca, though immense Chilean mills are still in use, with concentrators, the Moore
filter has been added. Much of the improvement at Pachuca has been made possible by the introduction of electricity, and the cheeseparing of power, which has resulted in an increased production, so that with all the additions to the mills of the camp Pachuca still lacks milling-capacity. The needs will be even greater in the coming year with the new work that is in progress. Pachuca, though but two hours by rail from Mexico City, is not heralded in the newspapers as many of the other centres of the Republic, but it possesses more old dividend-payers than any. The Santa Gertrudis has paid big dividends for 30 years, and millions are distributed yearly by the San Raphael, Soledad, Sorpresa, Maravilla, Real del Monte, and La Blanca. It is again stated that New York capitalists are after an option on this mine from Francis Rule for $10,000,000. At Zacualpa, one of the interior camps of the State of Hidalgo, the Seguranza Mining Co., operating the old Corona property, has placed a contract through its president, George A. Wadell, of San Luis Potosí, for the erection of a 200-ton concentrating and cyanide mill.

In Guerrero the Maine & Nebraska Mining Co. is building two miles of railroad from Balsas to the Santa Lucia mine, where it is stated 250,000 tons of ore have been blocked out. It is proposed to erect a 200-ton smelter early next year. The Guerrero Mining Co., also operating near Balsas, under the management of T. E. Ritsour, is preparing to put in a 50-ton smelter. A 50-ton custom mill is being planned for the Real de Guadalupe. The Columna y Anexas, together with a 35-ton Chilian mill, concentrator, and cyanide plant, and the San Pedro y Anexas, have been consolidated with El Progreso under the name of El Progreso Mining Co., and systematic development will at once be inaugurated.

Another important merger has occurred at Cananea, Sonora. The Calumet & Sonora Copper Co. and the South Cananea Copper Co. have combined and will be known in future as the Duluth-Sonora Mining Co., with $2,000,000 capital, controlled in Duluth, Minnesota, with J. W. Norton as president. The Lucky Tiger, in Arizpe, made famous by the long fight for possession by its Kansas City owners, is said to be under option to New York capitalists for $4,500,000.

Mining in Chihuahua continues exceptionally flourishing considering prevailing prices of the metals, and while September showed no material improvement over the output for August, the production for the month of October so far promises to make it the banner month of the output, and increase in the output from small shippers is noteworthy. The reported sale of the Rio Tinto mines and smelter at Terrazas, about 25 miles north of Chihuahua, by Juan A. Creel and associates to Corrigan & McKinley, of Cleveland, Ohio, has been confirmed, and the new owners have already given orders for alterations and additions necessary to increase the capacity of the smelter to 250 tons. For the economical handling of the ores a tunnel has been started to cut through a small mountain between the smelter and the mines, so that the ores may be taken directly from the mines to the smelter by a light Porter engine. The development of the San Rafael, in the same camp by the same people, continues with encouraging results, and large bodies of lead carbonate are being developed. In Santa Eulalia the American Smelting & Refining Co. is increasing its shipments, as is also the Buena Tierra of the Santa Eulalia Exploration Co., and the first named is putting in the tramway which arrived October 1 in six carloads from the Trenton Iron Works, of Trenton, New Jersey. This is to connect the A. S. & R. Co. mines with the railroad at Santa Eulalia, and may later be extended to the Company's Chihuahua plant. A. F. Palmer continues to send out several carloads per month of 50% zinc ore from the Coyame district, east of Chihuahua. The Chihuahua Copper Mining Co. is sending two carloads per week of 10 to 15% copper ore from Falomir to the Aguascalientes plant. From west of Chihuahua the Dolores Mines Co., the Republica, and the Rio de Plata are each sending about a carload per week, which net them $25,000 per car. The Calera Mining Co. continues sending cars steadily shipping a carload per week of clean galena and clean zinc-blende. Shipments of silver and gold bullion from the western part of the State through the city of Chihuahua to New York are nearly $500,000 per month. J. G. Stevenson is making cyanide tests at the Gavilana mines at San José del Sito; J. J. Watterson is putting in a 25-ton reverberatory furnace at Urucachi; S. L. Pearce is buying machinery for a mill at Chipinas; the International Gold Mines Co. of Kansas City, is said to have purchased for $200,000 from J. W. Pender the Socorro mines in the Rayon district, near Ocampo; and Bert Peterson, of Parral, has taken over a large group of claims at Los Lamentos, 50 miles east of Ahumada.

The Parral Consolidated Mines Co. has been organized with Philadelphia capital of $200,000 to operate La Prieta mine, with D. H. Bradley, Jr., as manager. Among other plans of the Company is the installation of a crusher, sampler, and belt ore-sorter. The Alvarado Consolidated Mines Co. has been re-organized in Boston, with a $10,000,000 capital, to work the Palmilla mine of Pedro Alvarado on the 18-year lease that was held by J. A. Coram. This lease has been turned over to the re-organized Company, of which A. J. McQuatters is president, and Juan A. Creel, of Chihuahua, and James I. Long, of Parral, are among the directors. An adit will be driven from the west side to connect with the main Palmilla shaft, which will reduce the expense of pumping about 60%. It is said that Alvarado has spent in pumps more than enough to have driven this adit. The shaft will be re-timbered and as soon as practicable a 1000-ton mill will be erected at the mouth of the adit.

SALT LAKE, UTAH.

Consolidated Mercur is the principal exclusive gold mine now active in the State of Utah. Next in importance are the Jennie, at Gold Springs, Iron county; the Annie Laurie, at Kimberly, Flute county, in what is known as the Gold mountain district. In the same region is the Sevier Consolidated, to which I referred in another letter as being a
good example of how a mine possessing merit may be ruined by incompetents. In this instance the property fell into the hands of persons who had had no previous experience in mining. They thought they knew enough to get along by themselves without employing a mining engineer to guide them; only to find out too late how serious a mistake they had made. The president of the corporation was formerly an employee of standing at Washington, and it was through him nearly $200,000 was raised for the purchase of the property, equipment, and development. After a time, the management was given to a minister of the Gospel, with the idea of putting the mine to use to expose the cause of religion. One only result could be expected—the mine is now held by its creditors. But Consolidated Mercur is unlike the others, in that its ores contain nothing but gold; in the others the gold is invariably associated with silver. From the annual report issued recently by the Consolidated Mercur company, it is ascertained that the ore treated in the mill during the fiscal year ending on June 30 last, averaged $2.77 per ton; that 92% of this went into the tailing, leaving an extraction of $2.85 per ton. A total of 226,229 tons was treated, of which there was $7,492 tons of base and 128,737 of oxidized ore. The slime-plant, installed last year at a cost of between $35,000 and $30,000, did not come up to expectations as far as the treatment of base ore is concerned; but the result obtained with oxidized ores is as satisfactory as that of the Consolidated Mercur company, which include $444,385 from the sale of gold bullion were $559,941. The net operating expenses were $657,504, leaving net earnings for the year of $2,436. Large expenditure was made in the development of new resources in the Brickyard mine, and in the re-opening of the old stopes in the Golden Gate mine, leaving a condition favorable for profit-making in the future.

Two mining deals have been consummated during the past fortnight involving property in the Tintic district. Control of the Caris mine has passed to C. E. Loose, of Provo, Utah, and associates, and the Opex group in the same district to Jesse Knight, of Provo, and associates. The Opex Consolidated Mines Co. has been formed to operate the latter, which is to be under the management of Frank P. Swingle, of Salt Lake.

The Tintic Smelting Co. will resume operation with one lead furnace within a week. Owing to inefficient power facilities the plant was recently closed, but the deficiencies have since been remedied.

A new hoisting plant has been installed at the Utah, United Mines Co.'s property in Beaver county and a vigorous development campaign has been planned. The Utah United corporation was formed recently as a result of a consolidation of the Skylark and Wasatch mines.

**BUTTE, MONTANA.**

*British Butte Mammoth Gold Dredge.*— *North Butte Extension Reorganization.—Anti-Wildcat Association.—Smelter at Cook City.*

The big gold dredge, one of the largest in the world, which is being built a few miles west of Butte by the British-Butte Mining Co., is assuming shape rapidly. People are beginning to wonder if they really had been looking at a bonanza right at the doors of Butte only to permit a lot of Londoners to pick it up without a protest. The British-Butte Co. is making a grand expenditure of $800,000, or about 1000 men, in the vicinity of Rocker, five miles west of Butte. In the pioneer days of mining considerable placer gold was taken out of the ground there, along what is known as Silver Bow creek. A false bedrock was reached and mining stopped. The British-Butte Co. has sunk a shaft through the false bedrock to a depth of 650 ft. From the bottom of this shaft a large amount of gold was seen on the surface, and yet the true bedrock has not been found. Through every foot of the shaft and bore it is said that gold has been found, and the fabulous yield of 33 to 50c. per cubic yard is reported all the way down. The dredge has a guaranteed capacity of 2500 yd. per day.

The stockholders of the Butte-Radersburg Mining Co., at their annual meeting, elected the following directors: F. H. Symons, Charles D. Horton, E. R. Dornblut, E. E. German, M. J. McEvans, Michael Morley, and L. E. Symons. F. H. Symons is president, M. J. McEvans vice president, H. A. Newcomb secretary, and L. E. Symons treasurer. The property is situated near Radersburg, Montana, and some development work has been done on it. The showing in gold and silver is said to be encouraging.

Butte shareholders of the North Butte Extension Copper Mining Co. are in receipt of notice from the reorganization committee, which was appointed at a meeting of directors in New York recently, concerning the plans to revive the Company. The committee is composed of George N. Orcutt, general attorney for the Erie railroad; R. J. Horner, of Horner & Co., of New York; Charles H. Moore, A. M. Andrews, and J. O. Morris, of Chicago. It is proposed to organize a new company under the laws of Maine to be called the North Butte Extension Development Co., with a capitalization of $1,500,000, divided into 1,500,000 shares. It is proposed to exchange the new stock for the old, share for share, upon payment of 50c. as an assessment. It is proposed to use the first $50,000 received to pay off pressing obligations and then to advance money as required to meet other debts and provide a working fund. It is stated that the subscribers to "pertain claimants and creditors" of the North Butte Extension Copper Mining Co., whose identity is not disclosed, have agreed with the committee to exchange their indebtedness and claims owing them, amounting to $75,000, for 150,000 shares of stock of the new corporation. It is also provided that the portion of the 1,000,000 shares of stock to be issued that are not taken by stockholders and the 550,000 shares that are not to be issued, shall all remain in the treasury of the new corporation as treasury stock, to provide for the future needs of the Company.

Mining men of Montana and other States in the Northwest have inaugurated a movement for the organization of an association, the purpose of which is to inject a little more honor into the business and to discourage frauds and "wildcatting." Each member of the organization is required to "pledge his honor as a man that he will so conduct himself in relation to the business of mining as not to reflect unfavorably on mining as an industry, and that he will not knowingly engage in any practice that will bring reproach upon the association." It is proposed to include in the association Montana, Idaho, Washington, Oregon, Alberta, British Columbia, and Alaska. With a large membership it is believed that more than half of all the mining in the United States than has been through any other association. The organization will be given considerable aid in its purpose to prevent fraud in mining enterprises by the coming legislative assembly of Montana, as many plans are being discussed by which laws may be made to reach the crook in mining promotion. The Butte district has suffered severely during the past two years from fraudulent mine promotions, and through failures of companies resulting from criminal recklessness and dishonesty.

Preparations are being made for the erection of a 200-ton copper smelter in the New World mining district near Cook City. Sufficient money for the enterprise has been subscribed, and the machinery has been hauled to the smelter. The location will be near the Scotch Bonnet property that will furnish the metal ore and is to be erected in the new plant.

The Baltimore Copper Mining Co. has made the final payment on the Baltimore claims near Boulder. The property has been partly developed by means of five adits, having an aggregate length of 1800 ft., and by a shaft and cross-cut. The ore assays well in silver, copper, and lead, and a considerable tonnage is claimed to be in sight.

It is reported that the re-organizers of the Davis-Daly Co. have become entitled to about 60,000 shares of stock by reason of the fact that stockholders of the old Company did not offer their shares for exchange together with the first payment of the $2 assessment levied.
JOHANNESBURG, TRANSVAAL.

Cheerful Outlook.—Nine New Mills.—Rhodesian Progress.—Community of Prospectors.—More Heavy Stamps.—A Natal State Mill.—Central Electric Station.

No report dealing with technical matters upon the Rand today should omit reference to the improved financial position and to the strength, gained rapidly after two or three years of increasing depression, maintained in the Kaffir-share-market. Many projects of expansion have been held over for ‘better times,’ but the ‘better times’ have been delayed first by labor difficulties and then by the disfavor in which all South African enterprises were held for a while among investors. It is difficult for men in other parts of the world to realize how keen was the depression upon the Rand during that period of exceptional industrial activity which marked the progress of mining elsewhere up to the autumn of last year. Now, however, there has been a manifest return of confidence. The deplorable elements of a boom are fortunately lacking. Few new stock issues are being thrown upon the market. Old established companies, controlled by the big and most reputable mining houses, are the leading favorites. Many stocks have advanced in price 20 to 40% in the last few weeks, several purely on account of the general buoyancy of the market; others in view of actual improvements from development. Revival of interest in Rand finance will naturally hasten the schemes of mining expansion resolved upon by numerous interests. But, even part from the influence of the market improvement, the promise of increase in the gold output during the next few months is assured. According to Government returns, there were $590 stamps and 86 tube-mills at work in July, treating 1,527,000 tons for a yield of 561,703 fine ounces, worth $2,855,862. New mills which have started crushing but have not yet declared their yields owing to the allowance of gold necessary for setting the plates and for the zinc-boxes) include those of the Simmer-Deep-Jupiter, West Rand Consolidated, and Aurora West; those erected and to commence work shortly, include the Gedould, Knight Central, Main Reef West, and Cinderella Deep. These plants comprise 720 stamps and tube-mills, and should swell the monthly tonnage of ore milled by about 160,000 tons. In addition to these, there are new plants and extensions under design or construction amounting to 175 stamps plus tube-mills. A dozen or more mines are erecting additional tube-mills to increase stamp-duties and extraction. Moreover, if the financial situation continues favorable, and Sir J. B. Robinson is able to raise the funds for carrying out his long-formulated policy in the West Rand, the Randfontein group of mines will next year see under way the erection of batteries totaling 800 stamps and 30 tube-mills, upon subsidiary mines at present not producing.

The large influx of miners, prospectors, and small capitalists to Southern Rhodesia during the last year would be an affair of much over-rated importance if unattended by tangible results in the shape of increasing output. Fortunately, the stimulus provided to mineral development by favorable laws and open prospecting is being reflected in a steady advance in production. The figures for the first seven months of this year compare satisfactorily with previous returns, as shown by the following records for Southern Rhodesia:

The rate of gold production may now be placed at about two and three quarters millions sterling per annum. In addition to gold, a yield worth £79,000 for the seven months is attributed to other mineral products, including, silver, lead, copper, chrome-iron, diamonds, coal, and a few tons of asbestos. The July declaration of mineral output was a record for the territory.

Considerable interest has been evinced locally by the publication in the South African Mining Journal of quotations from T. F. Van Wagener's article in The Mining and Scientific Press, in which he pointed out the direct influence of liberal laws upon the existence of a body of good prospectors in a country. It has often been declared by the representatives of the ultra-conservative Dutch farmers that the policy of 'open prospecting' would, if instituted, be fatal, according to the abolition of suitable authority, resulting out forcibly that a sound community of prospectors soon springs up when given a 'square deal.' This expression of opinion by Mr. Van Wagener proves welcome since the views of our public men are commonly influenced by the bias of party politics.

Just as tube-mills constituted the most significant factor in the progressive changes marking Rand metallurgy in 1905 and 1906, heavy stamps are the most conspicuous innovation of today. Excepting one or two mining groups, that are notoriously slow in adopting new technical policies, all the Rand corporations are equipping their new plants with stamps of a weight far in excess of the maximum of a few years ago. A battery destined to shortly commence work (upon ore held at 4000 ft.) is that of the Cinderella Deep, which mine has obtained special permission to stop and mill on a moderate basis through its single shaft; its workings being at present unconnected with any others, the Government could only suspend its regulations to a certain degree. However, it is estimated that 12,000 tons per month can be dealt with under existing conditions. The 50-stamp mill at this mine (to be extended to 100 and then to 200 heads when practicable) will be electrically driven, each unit of 20 stamps having its own 300-kw. motor, as compared with the 10-stamp units of the Simmer-Deep Deep plant. The weight of stamps will be 1700 lb., and these being aided by two small tube-mills, the anticipated stamp-duty of 8 tons per stamp per diem should be well maintained.

The earnest wish of the Natal Government to aid the development of metalliciferous mining in the Colony (whose mineral yield is almost negligible, with the exception of coal) has long been practically evinced by grants for diamond-drill prospecting and offers of bonuses. Another step has been made in the right direction by the acquisition of a Tremain mill for the purpose of conducting test-crushing (free of charge) in promising gold districts. This is certainly a small advance toward the policy of erecting test-crushing batteries of more or less permanence, as followed so extensively in Australia; if a comparison is to be established, however, it must be allowed that the finances of the Colony do not justify heavy expenditures, and the worth of its auriferous deposits has not been sufficiently demonstrated to encourage the risk of much public money. Consequently the Mines Department can as yet only lend aid to work of a preliminary nature by exploration, framing accordingly stipulate for the treatment of not more than 500 tons of any one deposit, and for the erection of the mill on not more than one site in the same locality, without exceptional case. Claim-holders whose property is selected for operations will be called upon to provide a suitable site and water supply, which must be available for use in the treatment of ore from other workings.

A large party of members of local engineering societies visited the new power-plant of the Victoria Falls Power Co. at Bralman (East Rand) last week. This is the first central station in which power will be generated by turbines in the Transvaal. The installation, designed for an output of 6000 kw., includes eight Babcock & Wilcox boilers, two turbines built by the Austrian Elektricitats-Gesellschaft, Berlin, coupled to three-phase generators of 3000-kw. capacity at 10,000 volt, and a power-factor of 9.8 running at 1500 revolutions.
Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Tin in the Lost River mine, Seward Peninsula, Alaska, occurs as cassiterite (tin oxide) in a greisen dike penetrating limestone, and with it is found an average content of 2% wolframite (tungstate of iron). Topaz is also a distinctive feature of the vein.

Volume decrease for tailing containing a moderate proportion of argillaceous material, upon drying from a saturated condition to the condition known as 'air dried,' is approximately 14%. Successive wetting and drying causes packing of the mass, resulting in a contraction which may amount to as much as 20% of the original volume.

The Bell-Krupp process of iron purification is a method invented by the late Sir I. Lawthian Bell to eliminate silicon and phosphorus from pig-iron. The liquid pig-iron is violently stirred up with iron oxide. The resulting silica and phosphoric acid are slagged off in from 7 to 10 minutes, the elimination of these impurities reaching 90%. The process is stopped as soon as the carbon begins to burn. The apparatus used is the revolving hearth of a mechanical puddling furnace. The metal so purified is used partly for the subsequent manufacture of crucible steel, and it is also employed in foundry practice.

Boulder blasting is best done by the method known as 'block-holing,' and 75% dynamite should be used. 'Mud-blasting' or 'sand-blasting,' also called 'bulldozing,' is exceedingly wasteful of explosive. This method depends upon the suddenness of the explosion from the detonation of the dynamite, and the only advantage of the mass of damp material placed over the cartridge laid on the surface of the boulder is to increase the area which is suddenly lifted, thereby increasing the resistance due to the inertia of the surrounding air. The force of the explosive is thus expended somewhat more effectively in overcoming the cohesion of the rock.

Shear, in geological parlance, expresses a form of cleavage in rocks resulting from a movement similar to that which would occur in a mass of rectangular outline if force were applied at one corner, altering its shape to that of a rhomb. Rocks so affected present a sheeted appearance. A region that has been subjected to shearing action usually shows a tendency to rotation around an axis, that is the shear-lines are curved, although this may often be recognized only on platting a survey of a large area. Within the sheared area lines of weakness in the rocks yield to complicated deformation, and are generally referred to as 'shear-zones.' These readily become places for the deposition of ores, partly because they are usually more permeable, and because the crushing and pectoidization of the minerals favor chemical interchange.

A claim located so as to include within the monumented area more ground than may be legally appropriated under the mining law, is liable to be curtailed by a subsequent location claiming part of the lode attempted to be covered by the prior claimant. Two remedies are possible in such a case, either to make an amended location accurately covering that part of the lode which is of the greater importance to the claimant, or by having the claim surveyed for patent by a Deputy Mineral Surveyor. In such a survey the full legal claim will be established within the monuments on the ground, and in the absence of conflicting claims the original locator may elect which portions of his claim, in excess of the legal area, shall be forfeited.

Permeability of concrete by water is greatly reduced by the addition of hydrated lime to the cement-mortar. The permeability is lowered to nearly nothing with 16% lime, a desirable mixture for this purpose being, cement 1 part, sand 3, stone 5, hydrated lime 1.5. The addition of lime, however, is generally regarded as tending to weaken the concrete, since free lime absorbs carbonic acid and gradually forms lime carbonate, accompanied by increase of volume, which would produce internal strains. Contradictory results have been reported in regard to the ultimate effect of using lime in cement-mortar. In recent tests made by the Boston Elevated Railway Co. it was shown that concrete 1:2:4, without lime, passed 74.8 grains water per hour through an 8-in. block at a pressure of 60 lb. per sq. in., while a similar mixture, plus 10% lime, passed only 1.6 grain under like conditions.

'Alkali' in soils consists of salts of lime, magnesia, potash, and soda. In 'white alkali' the salts are chiefly chlorides and sulphates, with some carbonates. 'Black alkali' consists almost wholly of sodium carbonate, but this may exist along with such quantities of other salts as to obscure its presence except on chemical test. The origin of alkali has not yet been satisfactorily explained. It is not due to a predilection of the salts named in the rocks of the arid region. In humid countries leaching by rain-water removes such material, the carbonic acid in the water assisting to an important extent. The crystalline rocks contain chlorine and sulphur, the average content in these elements being respectively 0.07 and 0.108%. The hydrolyzing action of water converts these into hydrochloric and sulphuric acids during the process of rock decomposition, and the corresponding salts are formed at once from the bases present in the constituent rock-forming minerals. During the prolonged seasons of drought capillarity brings salts from great depths to the surface, where they are left by evaporation. Many complicated chemical reactions and some remarkable physico-chemical phenomena, take part in the process. From the above it is seen that it is the aridity rather than a peculiarity of rock-composition which causes the accumulation of alkali in soils.
Discussion.

Readers of the Mining and Scientific Press are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

Shasta County as a Smelting Centre.

The Editor:

Sir—Shasta county, California, after having had a set-back in the smelting business by the farmers who were anxious to sell their land by means of damage suits against the smelters, on account of the smoke, now realizes the value of the smelters to itself and to the State. The majority of the people are in favor of encouraging the industry, even with some inconvenience to themselves, as the closing down of the Mountain Copper Co.’s plant at Keswick checked the business industries of the county much more than they anticipated. Since then, the Mammoth Copper Co.’s smelter, built during 1905, got fairly under way in 1906, and continued to increase its capacity until it reached a production of 3,500,000 lb. copper in May last, or at the rate of over $5,000,000 per annum, the ore smelted containing some gold and silver. Last June the Company was smelting at the rate of 1300 tons of local sulphides and 350 tons silicious ore. The silicious ore comes mostly from the Company’s own mines in Utah and Nevada.

The Balaklala Co., Copper Co. expects to start the smelter at Coram this month, with a daily capacity of 1200 tons. The Bully Hill Copper M. & S. Co.’s smelter was blown in again last March with one furnace, although I understand they have two, with a daily capacity of not less than 600 tons. This plant had remained idle for more than two years while developing the mining properties and constructing a standard-gauge railroad from the main line of the Southern Pacific to the smelter, at a cost of about $500,000. The Bully Hill ore averages richer than that of the three companies first named, on account of the ore containing more silver and gold. The mines are on the east side of the Sacramento river, not far from the Great Western Gold Co.’s properties (generally known as the Afterthought group), in apparently the same formation as the mines of the three first-mentioned groups. An igneous rock lies below the ore, with a sedimentary capping.

I particularly wish to draw attention to the necessity for more railroads for Shasta county and northern California. Three years ago, when I first came to Redding, the town claimed to be the fourth largest shipping centre in the State. Since then the Mammoth smelting works have been started, and have been operated continuously; the Great Western Gold Co.’s smelter was in operation every year during the dry season, but found it impossible to operate during the wet or winter season, on account of being situated 13 miles off the nearest railroad. Few people realize the freight business that one smelter will create. To illustrate, consider the case of the Mammoth. It requires 20 ears daily of 50,000 lb. capacity to bring in its silicious ore and coke and to send out its copper bullion. In addition to this there are supplies and machinery for the mines, and a business community built up by the employment of 1000 to 1200 men with their families.

The Redding, Afterthought & Northeastern Railway Co. has been organized to continue a road, first from Bella Vista to the Great Western Gold Co.’s smelter at Ingot (Bella Vista being already connected by a standard-gauge railroad with the main line of the Southern Pacific) and then, as
rapidly as possible, to extend the road farther to the northeast. At Ingot the railroad will get the business of the Great Western Gold Co., that is, blast furnace coke, silicious ore, and supplies. Outward the freight will consist of copper matte and selected zinc ore, too rich in zinc to justify sacrificing it in the blast furnace. While Ingot is the terminus of the railroad, the Terry Lumber Co. intends to make that station the lower end of its flume to load lumber onto the cars, instead of using Bella Vista, as at present. J. E. Terry claims that they could, if necessary, ship 20,000,000 ft. of lumber per year. In addition to the Terry Lumber Co., several other smaller lumber companies, with sawmills, are anxiously waiting for the railroad to shorten their haul on lumber, which they are now delivering by wagon. The road should be completed as soon as possible through the northeastern portion of California, and ultimately into south-eastern Oregon and southwestern Idaho. By extending the road 15 to 25 miles above Ingot, it would tap the best lumber region, with an estimate of 2,000,000,000 to 4,000,000,000 ft. of standing timber. This would give the agricultural valleys tributary to such a point a chance to market their products profitably.

It seems that Shasta county as a custom smelting centre has been overlooked by the American Smelting & Refining Co., for even when the Guggenheims had control of the Balakala smelter their idea seemed to be to have their large custom works at San Bruno, near San Francisco. I suggest Shasta county for many reasons: one is the advantage of being close to a supply of basic ore. In fact smelters on San Francisco bay are now compelled to either smelt nearly barren quartz, mined locally, or ship in silicious ore from Nevada and Utah. Redding is nearly as close to the mines of Nevada as is San Francisco. The Southern Pacific is now making the same rates on ore from Nevada to Shasta county smelters that they charge to San Francisco points. The damages from smelter smoke can be settled much more cheaply in Shasta county than in any other suitable centre in California.

I would not advise the erection of a smelter close to Redding, or anywhere south of it, on account of the fruit farmers. Up the Sacramento river, near Kennett or Coram (Keswick is too close to Redding), would be an excellent situation for a custom smelter, if competitive railroads had room to connect with the smelters without too great an expense. When the Redding, Afterthought & Northeastern railroad is completed in connection with the Terry Lumber Co.'s railroad, from Anderson to the Great Western Gold Co.'s smelter at Ingot, an excellent situation can, no doubt, be selected somewhere along that line where there are only a few ranches of small value which could be purchased above and below the smelter for several miles along the railroad.

The Redding, Afterthought & Northeastern railroad will no doubt be intersected east of Anderson by the electric railroad coming in from the south, and the Western Pacific from the southeast, in the near future. With such connections for California and Nevada at hand, the extension of the Redding, Afterthought & Northeastern railroad through the northeastern corner of California, southeastern part of Oregon and into Idaho would develop those regions and make a connecting link for the transportation of the ores of Idaho. The main-line railroads running north and south between Montana and Utah would not only be a good connection for the railroad, but would make another important feeder for a custom smelter such as the Guggenheims had in view for the coast.

Either San Francisco or Shasta county, California, are points much closer to the principal gold and silver mines of Nevada than Utah smelting points. It is true that Shasta county is back from the coast, but it is not far from where the Sacramento river becomes navigable. The low-grade ore-supply will naturally come from northern California, and mostly from Shasta county, where large orebodies are now developed.

San Francisco, October 10.

Dredging Possibilities in Sonora.

The Editor:

Sir—Replying to your editorial comment on my article on 'Dry Placers of Sonora,' I would say, that the problem of finding water for mining operations in the Altar district of that State is chiefly one of discovering subterranean reservoirs or buried valleys of adequate size, in which water is protected by a mass of sand or gravel from the intense evaporative power of the dry atmosphere of the Sonoran desert. Many such reservoirs are known and some have been tapped, but only on a small scale to supply water for a stamp-mill or a small battery of Huntington mills.

In some cases the mines are far from the reservoirs, and then the expense of several miles of pipeline must be met. The Magdalena and Altar rivers and their tributaries carry in their underflow large quantities of water, and this was utilized to supply the stamp-mill of the Llanos de Oro enterprise. It seems doubtful whether water could be pumped long distances from these gravel reservoirs cheaply enough for hydraulic mining, but there is no doubt that some of these placers will in the near future be exploited with dredges supplied with water from these subterranean sources. In the present lack of exact information it is difficult to form any reliable estimate of expense, but, in the writer's judgment, the possibility undoubtedly exists of operating placers with water at some points in Altar.

F. J. H. Merrill.

New York, October 5.

Cornish Pumps.

The Editor:

Sir—My belief that the prejudice existing against Cornish pumps is due in great measure to ignorance concerning them, is intimated by the letter on the subject appearing in your issue of August 1. Fortunately, the writer of that letter states that his experience with Cornish pumps has been confined to an
mining per the these must 'ornish vacuum would can the was seen saturated evaporated, the abandoned varnish. I think reciprocating handling cylinders the si 561 acid-resisting also com- is it aggravate

October 24, 1908.

MINING AND SCIENTIFIC PRESS 561

The occasional glimpse of one at some abandoned mine. This being so, it would probably have been wiser had we not proceeded to explain their working in an incorrect manner. It was wrong to base beliefs on these assumptions, and to conclude with a comparison of the maligned Cornish pump and the direct-acting steam-pump.

He states that the best results are obtained from Cornish pumps in perpendicular shafts where there is a permanent pumping-level. Just the contrary is the case, the Cornish pump being particularly suited for continuous sinking, and I had endeavored to emphasize this point in my previous letter, published July 11, by stating that pumps installed half a century ago, when it was expected to work the mines to no greater depth than from 600 to 800 ft., are today doing good duty to depths of nearly 2000 ft. I also hoped I had shown that Cornish pumps were exceedingly well adapted to handling sudden increases in the quantity of water, up to their maximum capacity. They have a large range of capacity, and will work economically from one-third up to full capacity by simply increasing the number of strokes. I also indicated how easy it was to increase the size of the poles when necessary to increase the capacity.

Your correspondent appears to think that the steam acts directly on the pump-rod, and by forcing it down raises the water. I must apologize for not having explained in my previous letter the modus operandi of the Cornish pump, and my excuse must be that I imagined that everyone interested in mine pumps was conversant with this elementary principle. I can imagine that it is owing to ignorance that so many people advocate the addition of a crank and fly-wheel to a Cornish pump. In the ordinary Cornish pumping engine, high-pressure steam is admitted to the top end of the inverted cylinder, and, assisted by a partial vacuum on the other side of the piston, forces this down, and with it the indoor end of the beam, thus raising the pump-rods and poles and drawing the water from the several cisterns into the pole-cases. A great part of the weight of this system is balanced by means of one or more balance-bobs. As soon as the piston has reached the bottom of its stroke, the engaging of a tappet opens the equilibrium valve, which has the effect of turning the exhaust steam from the upper end of the cylinder into the lower end, the result being that the steam-pressure is the same on both sides of the piston. The return stroke then commences, the weight of the rods forcing the poles into their cases and so raises the water in the main column.

After the return or outdoor stroke is completed, the lower end of the steam cylinder is placed in communication with the condenser, where a vacuum is formed. It will thus be seen that high-pressure steam plays no part in the pumping stroke of the engine, and for this reason the velocity of the rods on this stroke is practically the same, no matter how many strokes per minute the pump may be making. The speed of the pump, that is, the number of strokes per minute, is governed by the duration of the pauses at the end of each stroke. This is the crux of the whole system, and is the cause of the invariable failure of the crank and fly-wheel when applied to the Cornish pumping-engines. These pauses are governed by the action of the cataract valve, or in the more modern engines by the Davey differential valve, a most ingenious device, which I cannot attempt to describe.

It should be evident, therefore, that a Cornish pumping-engine operates with a variable speed, indoor stroke, depending for its speed on the point of cut-off of the steam in the cylinder, and a constant and comparatively fast outdoor stroke, with pauses of the required length between these strokes. No arrangement of cranks and fly-wheels will allow of this service, and the application of air vessels and other fakes in the endeavor to make them do so, is only to aggravate the error. Again, pumping by means of plungers is a reciprocating action, and so is that of the piston in the steam cylinder. Why introduce a rotary device between the two in a system of pumping that distinctly calls for pauses for its correct working?

Compound steam cylinders are frequently applied to the Cornish engines. Messrs. Hathorn, Davey & Co., have made a specialty of this practice, but it is doubtful whether greater economy in fuel-consumption results. For those who object to the overhead beam, and for very large plants it is no doubt objectionable; it is quite easy to have the cylinders placed tandem and horizontal, the piston-rod being connected directly to an angle-bob, which in turn operates the pump-rods. This system has lately been applied to one of the largest deep-pumping installations in existence, in a gold mine in Tasmania.

I regret that I know nothing of the high-duty, compound-engine, rope-drive connection to a gear- train and crank-shaft connected to Cornish plunger-pumps, as mentioned by another correspondent. It certainly sounds modern, and may be reliable and efficient. I should be glad to hear more about it, after it has been in operation long enough to demonstrate its value.

ERNEST R. WOAKES.

Linares, Spain, September 15.

Protective coating for cyanide vats which may be relied on, according to W. H. Gaze, is made by heating 80 lb. of tar in a water bath at 160° F., until all the water is evaporated, and then adding, with constant stirring, 80 lb. of natural cement, that is, hydraulic lime. The mixture should remain thin and fluid. Heat, and apply hot. No quicklime should be used. This varnish is acid-resisting and flexible. A good coating for wood vats is made of benzol, 3 parts; wax, 1 part; dammar or kauri gum, 2 parts. Paraffin may replace beeswax with advantage. Dissolve the dammar and wax in the benzol, and apply like a varnish. To close leaks in iron tanks, make a saturated solution of asphaltum in turpentine. Apply hot to the dry iron. Give three or four coats.

The yield of rubber per acre in the Malay States during 1907 averaged 130 lb., the extremes being 188 and 90.
BROMO-CYANIDING OF GOLD ORES.

By E. W. NARDIX.

*Although the bromo-cyanide or Dichi process for the extraction of gold from its ores is used at several of the Kalgoorlie mines, little information has been published on the original process, and no details are available from the various mines now using it. The following description of the process as carried on at the Hannan's Star plant, where several modifications were introduced by myself, will therefore be of interest. The process was first installed at the Hannan's Star mine, where a full working plant was erected by the London-Hamburg Co. In the contract 91% extraction on a sulphide ore of 15 dwt. value was guaranteed. This was considered a high extraction at the time, and the plant successfully fulfilled the promise made. The new features in the process were the finer grinding of the ore, for which purpose the tube-mill was introduced, and the addition of a solution of bromo-cyanide to the vats under ordinary cyanide treatment, whereby a higher extraction was obtained in a shorter time. The main difficulty in the process was in the manufacture of the bromo-cyanide solution, which was eventually overcome. The mixed salts now supplied by the London-Hamburg Co. are satisfactory, and are furnished at such a price that the process compares favorably with any other in point of cost.

Most of the Hannan's Star ore which has been treated by the process was low-grade, and hence the extraction is low, but the average value of the tailing for 1904 and 1905 was 1 dwt. 2 gr. and 1 dwt., respectively, which must be considered good work. On high-grade ore the process was equally successful. About 15,000 tons from the Brown Hill Extended mine, averaging 4 oz. gold per ton, and containing telluride, were treated by O. B. Ward in 1903, giving an average extraction of 95%. At Hannan's Star the average cost of bromo-cyanide treatment, extending over a period of 12 months (September, 1904, to October, 1905), was 9.75 pence per ton of ore treated, and the extraction was entirely satisfactory. On the same class of ore (sulphide), roasting would cost about 2s. 9d. per ton, so there is a balance of 2s. per ton in favor of the chemical, and the saving of the heavy first cost in furnace plant. In places where fuel and furnace supplies were more expensive, the chemical process would show a much more decided advantage. The process requires more metallurgical skill and constant attention to the progress of each vat under treatment; but, if this is available, the results are highly satisfactory, and the process has definite claim to be a cheap and efficient method of treatment for such ores as the Kalgoorlie sulpho-tellurides.

When I took charge of the Hannan's Star plant in July, 1904, the process was as follows: The ore from the rock-breaker was dry-crushed in two No. 5 Krupp ball-mills, with steel-wire screens of 27 mesh. From the mills it passed over amalgamated plates to a mixer, and then to a classifier at the end of the tube-mill. Here a separation was made, the overflow going to the slime-pumps, and the underflow into the tube-mill. The discharge from the mill was elevated to the classifier, where separation of the insufficiently ground portion was again affected. The slime-pumps delivered to two sets of spitzliten, the underflow from which passed back to the tube-mill, and the overflow to the pointed settling-boxes, where the pulp was thickened before passing to the agitator-vats. The point aimed at was to slime the whole of the ore to pass a 150-mesh sieve. In practice about 5% would remain on the 150-mesh sieve, but the whole of it would pass the 100-mesh sieve. There were four agitator-vats of 50 tons dry-ore capacity each. These each took an average 16 hours to fill, representing 75 tons per day through the ball-mills. The tonnage was determined, for working purposes, by weighing the contents of a bottle, filled to its containing mark by dipping into the vat, and by measuring the volume of pulp in the vat. From the volume, tonnage, and specific gravity, the dry weight of ore was obtained. A mechanical sampler was arranged between the ball-mills and the mixer, which cut out a definite quantity periodically.

This bulk-sample was quartered down, which gave the ore-sample for the day. A vat when full was given its charge of KCy, and three hours afterward a 'dip' KCy residue was taken, and the charge of BrCy solution added. After a total agitation of 20 hr., a quantity of lime was added, and the vat-charge 'pressed.' The quantity of BrCy added was varied according to the residue of preceding vats, and the value of the ore being treated as shown by the daily ore-sample. Every sixth frame in a filter-press was sampled, and the bulk-sample from the whole vat was quartered down to represent the final residue of that vat. The KCy residue was washed on a small vacuum-filter and assayed, while the final residue was assayed after drying. From the daily ore-samples, KCy, and final residue, the total extraction, and extraction by plain KCy, and by BrCy, were determined.

The bromo-cyanide solution is made according to the following equation:

(1) \[ 2KBr + KBrO_2 + 3KCy + 3H_2SO_4 = 3BrCy + 3K_2SO_4 + 3H_2O. \]

Its action in the treatment vat is supposed to be as follows:

(2) \[ BrCy + 3KCy + 2Au = 2KAuCy_2 + KBr. \]

The first two quantities in equation 1 are contained in the mixed salts supplied by the London-Hamburg Co., having about 40 to 44% Br as KBr, and 20 to 22% Br as KBrO_2; the proportion of Br as bromide being about twice that of Br as bromate. A 30-lb. charge is usually made up, and for this the following weights are taken:

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>H_2SO_4</td>
<td>50.0</td>
</tr>
<tr>
<td>KCy</td>
<td>20.0</td>
</tr>
<tr>
<td>Mixed salts</td>
<td>36.8</td>
</tr>
</tbody>
</table>

The KCy is 93%, and the H_2SO_4, 63% (chamber acid) strength. The solution is made in a closed wooden vessel, stirred by rotating arms, holding about 200 gal. In making up a charge, a portion of the water and all the H_2SO_4 are first mixed, and allowed to
cool to normal temperature. The KCy, which is d.s. solved in a separate vessel in sufficient water to fill, the mixing vessel, is then run in, and at the same time the proper weight of ‘mixed salts’ is gradually added. The whole is then agitated for 6 hr, before being used, and in a closed vessel it will retain its strength for some days. The cost of a 30-lb. charge of BrCy is about £4 10s., made up as follows: 50 lb. H₂SO₄ at 2d., 20 lb. KCy at 8d. 3½ lb. salts at 1s. 10d. From each charge mixed, a dip-sample is taken and tested with a standard Na₃S₂O₅ solution, using potassium iodide as an indicator.

(3) BrCy + 2KI = KBr + KCy + I₂

(106) (254)

(4) 2Na₃S₂O₅ + 2I₂ = 2NaI + Na₂S₄O₆

(316) (254)

Thus BrCy corresponds to 2Na₂S₂O₅.

The standard solution is made so that 1 c.c. contains 0.02 BrCy, and for this about 93.6 gm. of ordinary photographic crystals, Na₂S₂O₅·5H₂O, are dissolved in one litre of water.

A solution of copper sulphate is used for standardizing the above.

(5) 2CuSO₄ + 4KI = CuI₂ + 2K₂SO₄ + I₂

(126.8) (254)

126.8 Cu liberates 254.1, so that it corresponds to 106 BrCy and 496 Na₂S₂O₅·5H₂O. The solution is made by dissolving one gram of pure copper foil in acid, converting to sulphate, and dissolving in 100 e.c. water. Hence 10 c.e. contains 0.1 gm. Cu, equivalent to 0.0836 BrCy; then 1 c.c. hypo solution corresponds to 0.02 gm. BrCy, and 4.18 hypo solution to 0.0836 gm. BrCy.

In testing BrCy solutions, 5 c.e. are usually taken, Na₂CO₃ solution is added till alkaline, and then acetic acid till acid. A few crystals of KI, and some starred solution are added, and the whole titrated with the standard Na₂S₂O₅ solution.

Example: If 5 c.e. BrCy solution took 3.2 c.e. hypo, then

\[
\frac{3.2 \times 0.0836}{4.18} \times 20 = 1.28\%
\]

This method of testing BrCy solutions is different to that used at other mines, where it is customary to titrate directly with Na₂S₂O₅ without first neutralizing the H₂SO₄. The following is a series of tests made on a number of 30-lb. BrCy solutions by direct method, A, and, after neutralizing, B:

</table>

These show that by direct titration the test is usually low, and also that it gives irregular results, depending on the amount of free H₂SO₄ present. There seems to have been some doubt as to whether a BrCy solution increases in strength after, say, one hour’s agitation, but tests which were made show that it does increase up to about 8 hr, from 0.56 to 1% BrCy. It was generally known that if the solution became too alkaline, either through a change in the ores, or the addition of too much lime either to the ore before crushing or after the bromo-cyaniding treatment, the extraction by BrCy fell considerably, and for this reason an occasional test of the plant-solution was made for alkalinity, but not until several high tailing-discharges had been observed. Under the old system the KCy did not have sufficient time by itself: the gold in the ore and the KCy residue of each vat were not known, and the amount of BrCy that should be added was more or less a guess. When it is remembered that every 5 lb. of BrCy added to a 50-ton vat represents a cost of 4d. per ton of ore, that the action of the BrCy can be made just as effective after long KCy treatment, and that excess of BrCy gives no advantage, it will be seen how important it is that the value of the KCy tailing should be known after sufficient agitation (say 12 hrs.), and the condition of the vat tested as to alkalinity before adding the BrCy. In any case, the action of the BrCy is of short duration, not exceeding 4 hr.; so that if 20 hr. total agitation can be allowed, it is better to give 16 hr. with KCy, and then add the BrCy. It is preferable, however, to keep the vat under KCy treatment until the KCy residue is known, then correct the alkalinity, and add the BrCy. This could easily be done with extra vat-capacity. Total alkalinities are determined with standard solutions of HCl and Na₂O, using phenolphthalein as indicator. The following experiments were carried out to determine what was the most suitable degree of alkalinity for bromo-cyaniding.

Six sludge samples were taken at the same time from a vat which had had KCy treatment. The solution was filtered off one, and the quantity of a weak H₂SO₄ solution required to nearly neutralize it was determined. It took 40 c.e., so that to the sludge samples were added the following quantities of H₂SO₄ solution, respectively: to No. 1, 40 c.e.; to No. 2, 35 c.e.; to No. 3, 26 c.e.; to No. 4, 21 c.e.; to No. 5, 14 c.e.; to No. 6, 7 c.e.; to No. 7, nil. To each sample was also added 7 c.e. of BrCy solution, and the bottles were sealed and agitated for 8 hr. The solutions were then poured off and tested for alkalinity, while the residues were washed and assayed. The following were the results:

<table>

The KCy residue of the vat was 2 dwt., the final ‘press’ tailing 1 dwt. 9 gr., and the alkalinity of the solution from the KCy residue was 0.08%, and these are included as No. 7 in the above table. From these tests it will be seen that as the alkalinity was reduced so the residues fell in value in almost exact proportion; they prove conclusively that BrCy does not act well in a too alkaline solution, and that the
best action is obtained when the alkalinity is from 0.01% to nearly neutral.

A second series of tests, on a different grade of ore (assaying about 14 dwt.) was made. As in the previous case, varying quantities of \( \text{H}_2\text{SO}_4 \) and 7 c.c. of BrCy were added to the bottles, agitated for 12 hr., and the residues washed and assayed.

The KCy residue in this vat was 4 dwt. 12 gr., and the final press tailing 1 dwt. 9 gr. It became the practice, therefore, to have the alkalinity of the vats during KCy treatment at between 0.02 and 0.03%, to keep the vat agitated until the value of the KCy residue was known, then correct the alkalinity to about 0.01% or less by \( \text{H}_2\text{SO}_4 \), and add BrCy, according to the assay value of the KCy residue. A better extraction was thus obtained, at less cost for BrCy, at the expense of a small amount of \( \text{H}_2\text{SO}_4 \) and extra agitation.

Owing to an insufficient number of vats, they could not always be kept back for the KCy residue, but on every occasion on which it was done a certainty could be made of the tailing being low and the consumption of BrCy a number. A number of experiments were carried out to explain this reduced action in an alkaline solution, but nothing definite was proved, although it is possibly due to the presence of KHO. If a solution of KHO be added to BrCy it is almost immediately destroyed. No smell of BrCy is left, and no test can be obtained with \( \text{Na}_2\text{S}_2\text{O}_3 \).

(5) \( \text{BrCy} + 2\text{KOH} = \text{KBr} + \text{KCyO} + \text{H}_2\text{O} \).

Various experiments were carried out to determine the action of BrCy on FeS and finely divided metallic Fe. The FeS used was passed off from finely crushed ore, while metallic Fe was picked by a magnet from the sludge in a vat. Freshly prepared iron filings were also tried. Small quantities of these were agitated with a previously tested BrCy solution. Action once began, and in a short time the BrCy was destroyed. All smell of BrCy disappeared, and no test could be obtained from \( \text{Na}_2\text{S}_2\text{O}_3 \). The result is a greenish-blue solution of a ferrous salt, from which a dark-green ferrous salt is precipitated by \( \text{NH}_4\text{OH} \). These experiments showed that both FeS and metallic Fe are bromo-cyanicides, that finely divided metallic Fe is the more active, and that there is sufficient of the latter produced in grinding the ore to destroy the amount of BrCy usually added to a vat. The BrCy seems to act more by breaking up the FeS than by actual solution of the gold, but it is probable that a great portion of it is destroyed by the finely divided metallic Fe. without, of course, any beneficial result as far as setting free or dissolving gold is concerned.

Experiments were carried out to show the effect of adding ordinary commercial lime to vats after BrCy treatment, and it was found that a re-precipitation of gold took place to a small extent. To show this in a magnified way, two samples of solutions, A and B, were taken from a vat after BrCy treatment. Excess of lime was added to A, agitated a few hours, settled, decanted, and assayed, with the following result:

Solution A assayed 3 dwt. 21 gr. per ton ;
Solution B assayed 5 dwt. 5 gr. per ton ;
showing that the lime precipitated 3 dwt. 8 gr. of gold per ton from solution, or 23%. This is probably due to the presence of carbon or of occluded gases, such as hydrogen.

The results of these experiments have suggested certain improvements in bromo-cyanidimg, some of which have been adopted, as follows:

1. The daily ore sample should be taken in the morning, and assayed as soon as possible, so as to know the value of the ore passing to the vats in the previous 24 hours.
2. The pulp should have a long KCy treatment.
3. A vat should be kept under KCy treatment till the value of the KCy residue is known.
4. The alkalinity of the vat should then be determined and corrected to 0.01% by \( \text{H}_2\text{SO}_4 \), before adding BrCy.
5. The quantity of BrCy added should then be determined from the value of the KCy residue, the tonnage of the vat, and so forth.
6. The lime added to the ore during crushing should be varied according to the alkalinity-test after KCy treatment, so that the plant-solution tests about 0.02 per cent.
7. Lime water should be made and added to the vats or to the solution from the presses, instead of adding lime to the vats.
8. Metallic iron should be kept out of the pulp as far as possible, as it is both a cyanicide and bromo-cyanide.

Ordinary white alkali attacks and destroys cement concrete and probably some kinds of sandstone. The department of engineering and chemistry of the Montana State experiment station has arrived at this conclusion. This means that it is unsafe to use cement in any foundation or other structure coming in contact with soil in alkali regions unless some method is devised to protect it from the action of these salts. To devise some protection against this action of alkali on cement is the object of further investigation which the experiment station expects to carry on. The attention of the station was first called to this matter about a year ago by a letter from C. W. Swearingen, city engineer of Great Falls, to E. T. Tannatt, head of the engineering department of the station, asking him to investigate the cause of the disintegration of certain concrete sewers in Great Falls. Mr. Tannatt and Edmund Burke made a thorough investigation of the sewers referred to, and also of some concrete and sandstone foundations in the same city. These sewers, which had only been in a few years, were found to be in many places nearly destroyed by the action of the alkali in the soil surrounding them, and the sandstone foundation of the court house at Great Falls was found to be affected, both outside and inside. Similar action on cement has been noted in other places. Asphalt applied over the surface of the concrete affords a certain measure of protection.
DEEP LEAD MINING IN AUSTRALIA.

Written for the Mining and Scientific Press
By D. H. Browne.

"It was the Californian prospector, Hargreaves, who first publicly demonstrated the existence of gold in Australia. Actually the discovery by others seems to have occurred both in New South Wales and Victoria about the time of the rush to California in 1849. . . . Then, on April 3, 1851, Hargreaves appears on the scene and discovered the precious metal. The locality was near Bathurst. The news spread over the Colonies; a stampede to Bathurst and the adjacent districts occurred, to the distraction of pastoral settlers, and to the annoyance of the respectable government at Sydney."

The Rev. W. B. Clark, a geologist, gave excellent geological and political advice at the time in the columns of the Sydney Morning Herald. He sagaciously remarked that "the momentary effect of the gold mania may be to upset existing relations; but the effect will be a rapid increase of population and the Colony must prepare herself for an important growth in her influence upon the destinies of the World."

"Victoria was not long behind New South Wales in finding a goldfield, and it soon caused the older Colony to pale its ineffectual fires in the greater brilliance of the Victorian discoveries. James William Esmond was to Victoria what Hargreaves was to New South Wales. Esmond like Hargreaves had been at the Californian goldfields, and had an impression that the Australian soil was also auriferous. He left Port Phillip for California in June, 1849, observed that there were similarities in soil and general features between Clunes and California, and decided to return and explore his Australian home for gold. It chanced that Esmond and Hargreaves were fellow passengers from California to Sydney. Esmond found gold at Clunes, Victoria, on June 29, 1851. Gold was discovered at Ballarat, the native name for a 'resting place,' on August 25, 1851." Thus writes Withers in his 'History of Ballarat.' Victoria is the home of deep lead mining. It is interesting to trace what has been accomplished in developing this class of mining and the system successfully adopted to overcome the difficulties, which were so great that, in the light of our present knowledge, one can look back and admire the ability, judgment, and persistent effort displayed by the early pioneers, men of all nations, who in 50 years have built up a state of civilization of which every person in the country may well feel proud. When we consider that within four years of the discovery of gold at Ballarat, the miners on that field had traced the leads from the hills and flats, under the basaltic plateau, and that we find them putting down shafts through 400 ft. of hard rock, with the indomitable faith that gold would be found beneath; and then when 'wash-dirt' was struck, of which there was only..."
trommel which throws off the coarse stones, the sand and gravel falling through the perforations into a sluice with a fall of 1 1/2 in. per foot, and the flow of water carries away the sand and gravel and leaves the gold in the riffles, which are generally of the Venetian-blind pattern, except at the top, where ordinary rails are used. On the other alluvial districts of the State, elevators are not used, the dirt being puddled in layers, and the rough stones, which always rise to the top, are forked out two or three times until the machine is full. The gravel is then dropped onto a floor through a trap door in the bottom of the machine by sheet-iron scrapers attached to harrows, revolving at a slow rate of speed. It is then shoveled into a sluice under a strong jet of water, which acts in the same manner as the sluice at the head of the elevator above mentioned.

In the case of the Berry United Deep Lead, Ltd., controlled by Bewick, Moreing & Co., belt-conveyors are being installed for the purpose of elevating the puddled dirt, and it is generally considered that this method will be an improvement upon existing appliances. With the exception of these two innovations the plants for working deep alluvial mines are similar to those in use 40 years ago, only that the pumping engines in some instances are more powerful, where the leads have been traced into open country away from the ranges. In several instances triple-expansion high-pressure engines working 26-in. Cornish pumps have been installed to cope with the heavy flow of water in the old river-beds. In the early days the pumping was done in some instances with Cornish beam-engines and pumps up to 22 in. diam., and immense quantities of water were raised. But in most cases a single-cylinder horizontal non-condensing engine was used, but they proved expensive in fuel. The first company in the State to use a compound engine for pumping was the Chalks No. 3 at Carisbrook, which installed a cross-compound, with 16-in. high-pressure and 28-in. low-pressure cylinders, 4-ft. stroke, and having horizontal condensers. Three Cornish flue-boilers, 26 ft. by 6 ft. 6 in., at a pressure of 110 lb. per sq. in., gave ample steam to work two Cornish lifts 20 in. diam. to a depth of 270 ft., pumping the water 30% cheaper than any other class of engine. Other instances could be cited where compound and triple-expansion engines, working pumps up to 26 in. diam., have given satisfaction, and within the last few months Bewick, Moreing & Co. have installed at the Berry United Deep Leads, Ltd., a high-speed engine with rope gear to drive a 26-in. Cornish lift, in a shaft 600 ft. deep, and are pumping the water at one-third less cost than a cross-compound engine working a 22-in. lift of pumps at the other end of the same mine. This is the most important innovation in pumping machinery that has taken place for many years, as the cost of fuel is becoming a more important factor in the development of Australian mines every year, especially as the deep leads for the most part have been traced into the open country, and are overlaid in many cases with basalt 300 ft. thick.

The old rivers or leads take their rise in or close to low ranges of slate and sandstone, and gradually dip away toward the seacoast. In some instances, owing to volcanic action, the old rivers were faulted across, and one part tilted up, but otherwise not disturbed. In other cases dikes of basalt cut through the old leads and remained in the form of thick walls of rock, which greatly puzzled the alluvial miners of early days. In one break of this kind a stretch of channel a half mile long and 1000 ft. wide was engulfed, and remained as a formless agglomerate with ejecta from the volcano.

Of late years such rich pay dirt as was worked in the fifties has not come to light, nor even such gravel as was worked in the eighties by the Madame Berry lead in the Ballarat district. The phenomenal yields got at Ballarat in the early days, such as a pound weight of gold per pan, and nuggets such as the Welcome nugget, weighing 2217 oz., are only like a dream, but there still remains about 250 miles of deep lead to be worked. The great obstacle to the development of these old river-beds is the quantity of water contained in them, which in some instances has cost hundreds of thousands of pounds to drain the ground sufficiently to admit of testing the mine. But these leads have been so rich in their higher reaches that there is hope that history will repeat itself. Most of the best leads travel close to or along the back of the auriferous belt from which they took their rise. This is an important factor to be considered when estimating the chances of finding payable gold, as a lead which travels across the strike of the auriferous country is invariably of a patchy character, being fed from time to time by the gold-bearing strata over which it passes, whereas a lead traveling in the direction of venation has been fed on its course by the denudation of the auriferous ranges, which at one time stood thousands of feet higher than they do today.

As to the deposition of gold in these leads, there is one important fact which may be of interest, which is, that the best gold is not always found in the deepest part of the lead, it being sometimes on one bank and sometimes on the other, and then at times in the deepest part. It is now generally understood that, where these reef washes occur, the gold was originally laid down at a comparatively shallow level, and that at a subsequent period the river cut a new and deeper course for itself, sometimes outside the original bed, and in that case the deep channel will be found to be poor. At other times the deep channel would encroach on the original bed and wash away a portion of it. Then we may find the main channel payable, while in some cases the original channel is washed away altogether for a considerable distance, and all the gold is deposited in the deepest part of the lead. At other times the deep channel takes a sinuous course and cuts across the original formation many times, with the result that the gold is found alternately in the deep and then on the shallow ground. This shallow ground is termed 'reef-wash,' and near the source of the leads is similar to the placer mining of America. Waldemar Lindgren, of the United States Geological Survey, who reported on the deep leads of Victoria a few years ago, said: "I wish to reiterate my
admiration for the excellent work already accomplished, and my belief that deep-lead mining is an industry of incalculable value, well worthy of encouragement and protection. The gold-bearing region of California presents great similarity to that of Victoria in climate and geological structure. The reefs in California have been formed in exactly the same manner as those of Victoria, and their erosion has given rise to the same gold-bearing gravels, but greatest difficulty the alluvial miner in this State has to contend against is the immense quantity of water contained in the drifts overlying the wash in the gutters or ancient river-beds, and to cope with this water successfully and economically is the point to be aimed at by mine managers. If they thoroughly understand this part of the business, they will not only win credit for themselves, but will be the means of saving large sums of money for the companies they represent, and, in many instances, will make a success of a venture which otherwise might be stopped for want of funds before being properly proved. Of paramount importance in laying down the plan for opening up an alluvial mine is the determination by boring of the position of the deepest channel of 'wash,' as well as both banks of the old river (called 'rim' in California 'Blues-lead' mining), and note the depth of drift and gravel overlying the wash, since the quantity and pressure of water likely to be encountered depends largely upon the amount of drift met with. While mentioning drift, it is well to say that experience has taught us that what appears to be sandy clay in a bore has given as much trouble in sinking a shaft as the worst classes of 'drift.' It can safely be said that all managers and directors who have had experience in sinking a shaft through this material are agreed that the cheapest and safest course is to select a site for a shaft to one side of the lead and clear of all 'drift,' as immense sums of money have been wasted in sinking through drifts from 50 to 100 ft. thick. The difficulty consists in the soft material under pressure of water boiling up into the shaft. The matter of driving a few hundred feet is of little consequence, and will cost infinitely less than sinking a shaft through more than 10 or 15 ft. of drift.

While the foregoing will give some idea of the value of the gold-mining industry to this State, a few practical hints on the working of alluvial mines may be interesting to the younger generation of miners, who may be called upon to open up deep leads in countries where, up to the present, no attention has been bestowed upon this class of mining. The

---

**Fig. 1. Cross-Section of Deep Lead.**

I think it may be said that on the whole the deep leads of Victoria carry more gold per fathom than those of California. The skill and enterprise shown by the old-timers in overcoming the great difficulties of alluvial mining in the early days, notably at Ballarat, are truly admirable, and there has gradually been evolved a class of mining men second to none in solving the dangerous problems of handling the loose and water-soaked sands and gravels far below the surface.

While Victoria has a splendid climate, and good farming and grazing lands, the prosperity of the country still depends to a great extent on the gold-mining industry; the industry which made the country what it is today, which employs directly 25,000 men, and indirectly many thousands more. Since 1851 the output of gold in Australasia has exceeded £500,000,000, and Victoria can feel proud of the position it occupies in the industry, as it has contributed over £276,000,000, partly from alluvial and partly from quartz mining. The present annual output from all sources is valued at about £3,200,000.

While the foregoing will give some idea of the value of the gold-mining industry to this State, a few practical hints on the working of alluvial mines may be interesting to the younger generation of miners, who may be called upon to open up deep leads in countries where, up to the present, no attention has been bestowed upon this class of mining. The

**Fig. 2. Drift-Box.**

Where necessary, however, a shaft can generally be sunk with a properly constructed drift-box, such
as is illustrated by Fig. 2. The box is formed to suit
the size of the shaft being sunk, and should be made
large enough to receive another box inside of it
which would be the ordinary size of the shaft, as the
first box might become immovable before the re-
quired depth was attained. The box should be made
of steel-plate \(\frac{3}{4}\) in. thick, according to the size
of the shaft; depth of plate, 3 ft.; the side to be in
two pieces, joined together by a vertical plate 2 ft.
6 in. long, about 12 by 1 in., riveted to one part and
bolted to the other with \(\frac{3}{4}\)-in. bolts; the end to be
in three pieces, the two corner pieces to be about
1 ft. wide, to be riveted to the sides with 4-in. angle-
iron, and to have a piece of 4-in. angle-iron riveted
to the opposite edge, and bolted to the angle-iron on
the centre-piece at the end; and finally, a 4-in. angle-
iron to be riveted all round within 3 in. of the bottom
of the box. The timber, 12 by 8 in., should be bolted
with \(\frac{3}{4}\)-in. counter-sunk bolts 18 in. apart, the nuts
let into the wood on top of the angle-iron, on which
to place the screw or hydraulic jacks. All rivets
should be \(\frac{3}{8}\) in. and placed not more than 4 in. apart,
and counter-sunk at the back of the box. Bolted
all round on top and at the back of this box is a plate
3 ft. 6 in. by \(\frac{1}{2}\) in., with \(\frac{3}{8}\)-in. bolts, 9 in. apart.
fitted close at the corners. This part of the box
stands up behind the ‘slabbing’ of the shaft, the
slabs being cut to fit close to the plate so as to pre-
vent the ‘drift’ finding its way between the plate
and the slabs. Plates the full depth of the box are
best, if procurable. The sides complete, with corner
pieces attached, forming the ends, can be lowered
into the shaft in one piece and placed in position;
the two end-pieces are then sent down and bolted
to the corner pieces, and the box is complete, with
the exception of the strong centre-pieces, which
should not be overlooked. If the shaft is extra wide
it can be stayed by diagonal pieces of timber across
the corners of the box. Before the box can be low-
ered into the shaft, the shaft must be enlarged in
the clay which generally overlays the drift. As
soon as the box has been placed in position, a few
sets of slabs put between the shaft-timber and the
jacks completes the work and the box is ready to be
forced into the drift. Care must be taken that equal
or unequal pressure be placed on the jacks, so long
as the box is kept as near level as possible. The nose
must be kept well down in the sand.

The depth to the lead having been ascertained by
boring, and about 20 ft. added in case there should
be deeper ground between the bores, the shaft should
be sunk far enough into the bedrock to allow for a
rise in the bottom of the main level of about 2 in.
in each 100 ft., and to permit of the lead being
worked, say, a mile down the lead, or to the boun-
dary, if less than a mile. I have found that the
above fall is sufficient to provide a good gangway
for the trucks traveling each way. It also serves as
a good water-lodgment when the road is laid prop-
erly, and does not form a man-trap for the workmen
in the manner that drifts driven at a deeper gra-
dient do in wet alluvial mines. There might be
enough water in the chamber to drown a man, while
the drift a few hundred feet from the shaft would
be clear of water. It also means that all the silt
would find its way back into the shaft, instead of
settling along the main level, where it could be
easily and cheaply removed. In addition to the
lower level in deep and difficult alluvial mines, an
upper level should be constructed in the bedrock, for
two important reasons, (1) to provide an escape for
the men in case the mine should be flooded, and (2)
as a return air course. This applies to leads covered
with basalt particularly, where separate air-shafts
are costly to sink.

Many years ago it was considered the correct thing
to drive in the wash and meet the water in the face,
or to put up small rises or ‘bleeders’; but this course
proved so disastrous in many cases when going into
a lead for the first time, that it has been abandoned
by all managers of experience in favor of a series of
eased bore-holes. Boring for water in this manner
requires some experience, but the precautions neces-
sary to be taken depend somewhat upon the nature
of the bedrock through which it is intended to bore.
 Unless the country is hard, from 5 to 10 ft. of 4-in.
tubing is forced with a jack into a hole bored slightly
smaller than the tube. The tube is then wedged
round together at the back of the drift. A hole is
then bored with a smaller augur or bit, just large
enough to admit a 3-in. tube, the joints of which
have been fitted to run easily. The tube should also
be beveled inside at the upper end, and perforated
with \(\frac{3}{4}\)-in. holes for about 4 ft. from the top, so as to
act as a filter when the tube has been forced up into
the wash. The best length of tube is 5 ft., with a few
shorter lengths for matchings. A large nut is
screwed onto the male end of the tube to protect
the bottom thread while the tube is being forced.
This nut is 3\(\frac{1}{2}\) in. deep, made of wrought or cast-
iron bushed, the top 2 in. hexagonal in shape, 5 in.
diam., and the lower 1\(\frac{1}{2}\) in. square, and 7 in. diam.
Through the square position a slot 3\(\frac{1}{2}\) in. by \(\frac{1}{2}\) in. is
cut through to receive a slide \(\frac{3}{8}\) in. thick, should
the bore go through to sand instead of coarse gravel.
It is often impossible to plug a bore that is running
sand with a strong pressure behind it. It is neces-
sary, in soft gravel especially, to exercise great care
not to bore the hole too large for the tube, as the
water would then get outside the tube, and should
there be much pressure, the water would scour the
hole large enough to permit an inrush of sand. By
this system of tubing, in moderately firm ground the
water can be drawn off in quantities equal to the
capacity of the pumps; and should anything happen
to the machinery, necessitating a stoppage, it would
be found that part at least of the tubes could be shut
off with cocks without fear of causing the water to
flow outside instead of inside the tubes. But we
know that ‘the best laid schemes of mice and men
gang aft aglee,’ so it is necessary to make provision
in case an inrush of water and sand occur unexpect-
edly; the pumps may be protected from being filled
by sand. This is done by constructing strong locks
or doors at intervals along the drift. The ground
is cut out about 2 ft. into the sides, back, and bottom
of the level, and a heavy frame set, with two centre
pieces in it, placed in the excavation, and boarded up
close on each side. A door about 6 in. thick is hung with strong hinges in such a way that a man can close it easily behind him, being cut in two on the bevel in the same way as a stable door. These doors are not made air-tight, as the compressed air in the event of an inrush of water would blow them out. Experience has shown that where there are a number of these doors along a level, a large accumulation of sand may be found between the doors nearest the face, but the sand will not, as a rule, reach the pumps.

When the mine has been drained, or at least the great pressure of water taken off, and not till then, is it practicable to open up the lead in a systematic and profitable manner; but managers have fre-

quently found it difficult to convince directors and shareholders of this fact, so they have been forced to drive into the wash, with disastrous results to all concerned. The proper time to attempt to open up the wash is after several bore-holes have eased so much that they have started to draw in air, and the pressure-gauge indicates about 20 ft. of water above bedrock, and even then it is advisable to be extremely cautious and attend to everything likely to insure the safety of life and property. A short cross-cut should be driven off the main level at a point outside the deepest run of wash, and a door hung near the opening. A raise should then be constructed near the end of the cross-cut, and opened out in bedrock, the back of the drift being slightly above the level of the deepest wash proved by boring over the back of the main drift. About 12 ft. from the top of the raise another door should be hung, so that in case of a rush of water the men could close the door and so be enabled to descend the ‘jump-up’ safely.

In conclusion it may be remarked that deep-lead mining has been somewhat under a cloud for several years, but this is due principally to the great cost entailed in pumping out the heavy flow of water, and not because the gold-content of the leads is much inferior. These periods of inactivity have recurred at intervals in the past, and then some mine would make a discovery that would give an impetus to the industry sufficient to cause fortunes to be made and large areas prospected. At present the outlook is promising, as some of the mines with famous histo-

ries are approaching that stage when shareholders expect to be rewarded for their outlay.

Paper from rice straw is reported to be a commercial probability, according to experiments recently made at Bargor, Maine. It is claimed that $2 per ton may be realized in the rice straw which is now wasted.

Emery was produced in the United States during 1907 at but two localities—Chester, Mass., and near Peekskill, N. Y. The total amounted to 1069 short tons, valued at $12,294.

The world’s coal production during 1907 amounted to 1,269,184,109 short tons, of which the United States furnished 480,363,424, or nearly 40 per cent.
DECLINE AND REVIVAL OF COMSTOCK MINING.—II.

Written for the Mining and Scientific Press by Whitman Simmons.

In the early sixties, many mines put up their own mills, but the men who controlled the mines soon separated the mining from the milling business, and held the mills as their private graft. The 'bonanza firm' privately owned the mills that worked the Con. Virginia and California ores; they likewise owned the Omega mill, which worked the tailing from their other mills. By 1876, the Comstock mill-men had learned how to get a pretty good extraction from the ore. The best managed of these, the Lyon mill, at Dayton, was working sand-tailing that assayed $5 per ton for less than $2.50 per ton. As difficulty was experienced in buying $5 tailing, the extraction of the mills must have been good. Senator Jones, that is, he who became Senator Jones, worked some ore for Fair and Mackay, who did not happen to be interested in the mill, and they are said to have received in bullion more than 90% of the battery-pulp assay. On the Comstock the pulp-assays used to run about 10% below the car-samples, so that 90% 'battery-assay' represented about 81% of the value of the ore. The mines did not have their own assay-offices, neither did the mills, but there was a general assay-office for the mines and mills controlled by each 'ring.' The mines did not sample the ore shipments, but let the mill-men do it: this was in the interest of economy, as it was manifestly unnecessary for the same partnership to sample the ore twice. The mills were supposed to return to the mines in bullion not less than 65% of the average battery-assay (which would be equal to about 85.5% of the car-sample assay). There are but few examples on record where the mills returned more than they had to. In 1876 the Belcher mine shipped to the mills 131,328 tons of ore yielding returns of $2,920,460 in bullion, an average of $22.23 per ton. For milling the mine paid the sum of $1,534,925. The mills on the Carson river (putting through 4 tons per stamp, crushing to 6 mesh, and then re-grinding in pans) worked for about $3.50 per ton. At first they paid $2 for transportation, and later $1. They charged the Belcher $10 for milling and transportation, thus making a profit of $4.50 per ton, or $590,000. In 1876 they probably extracted about 85% of the battery assay-value and delivered to the mine 65%. Thus they retained 30% more bullion than they delivered to the mine owners. The mill profits were thus $590,000 from milling charges and $875,000 from excess bullion, making a total profit of $1,465,000 from the Belcher alone, while the mine accounts for the same year showed a loss of $600,000. Crown Point was similarly looted, and during the year its stockholders were assessed $500,000. These operations were made possible by the trustee system; the five directors of the Crown Point in 1876 held an aggregate of only 175 shares.

The Comstock mines, which produced more than $25,000,000 in 1875, produced only $3,300,000 in 1880, and $1,700,000 in 1881; in fact, at the end of 1880 not a stamp was dropping on Comstock ore—all the mines were exploring for new bonanzas between the 2000 and 3000-ft. levels. The profits of the mill-men had disappeared, so they began a new deal. In January, 1881, Sam Jones started 16 stamps at the Mexican mill on Crown Point ore, taking the poorer rock that formed the periphery of the old bonanza orebody, and which had previously been considered too poor to pay. In April the Vivian mill started on Belcher ore, and the Brunswick followed on ore from the Yellow Jacket. It was not long before the Belcher was producing as much as 6500 tons per month, Crown Point 6000, and Yellow Jacket 5000 tons. The bullion returned by the mills to the Gold Hill mines during the eighties generally averaged $12 to $18 per ton. Between milling charges, excess bullion, and false sampling, the mills were enabled to absorb everything in sight, and they had their trustees load on as many assessments as they thought the stockholders would stand. 'Low-grading' proved a great success; it was the counterpart of the modern 'high-grading' at Goldfield.

When Gold Hill was flooded for the first time in 1880, the managers probably thought it necessary to pump out the water and search for new bonanzas in order to find ore for their mills. When Gold Hill was flooded for the second time in 1882, they saw that pumping was unnecessary. They had then been milling low-grade ore from the upper levels for nearly a year. Why should they spend the assessment-money in pumping and in deep exploration, when they could divert an equal amount into the milling business, which was the same as their private bank account? Gold Hill remained flooded, and J. P. Jones carried the low-grade system into Virginia City. In 1885 he fixed up a deal with the Consolidated California & Virginia (consolidated November, 1884), leasing the ground above the 1550-ft. level at a flat rate of 50c. per ton, which was 3% of the bullion he says he took out. At the same time the Con. California & Virginia Co., having abandoned its lower levels to the flood, went to work on the 1750-ft. level. By April, 1886, when the middle mines were still struggling against the water and heat near the bottom of the Combination shaft, 'low-grading' was such a success that there was not an idle mill in the district. During 1887, 30,000 tons per month was being crushed. The bullion output of the Comstock slowly and steadily increased during the eighties, and in 1890 the Comstock was the liveliest mining camp in the West. But by that time the low-grade ore of the bonanza orebodies was nearly exhausted. What was stolen during this era will never be known. It is significant, however, that while in 1888 the mine accounts show a production of $5,500,000 in bullion, Wells, Fargo & Co. carried out $7,500,000, and this latter amount does not cover the midnight drives to the Carson Mint.

The monopoly of 'low-grading' was varied by the finding on the upper levels of some bonanzas that had been overlooked in the earlier days, and in consequence there were several stock deals that brought back the excitement of the sixties and seventies. It
is said that Senator Jones found a new bonanza 'fissure' just to the east of the old Con. Virginia stope.

charge of Con. California & Virginia. In two months Con. California & Virginia went from $1.95 to $35; Ophir went form 65 cents to $35. Hale & Norcross rose from 55c. to $9, and Best & Reeker, Savage, and several others went up similarly. The 'shorts' were trapped, and there were many failures among the brokers. Robert F. Morrow (the ablest operator on the street since James Keane went to Wall Street), who nearly always operates as a 'short,' is said to have an unpleasant recollection of the deal of 1886.

During 1887 Con. California & Virginia produced 125,876 tons of ore that assayed more than $30 per ton, and the mine yielded $3,527,000 in bullion. Dividends of $1,080,000 were paid. The next

year the same mine produced over $4,877,000, and paid dividends of $1,188,000. Hale & Norcross found a new bonanza on the 700-ft. level that brought the mine $840,000 in bullion for 1888, and paid $224,000 in dividends. Confidence was caught again, and in two months Confidence was sent from $8 to $32.

But these were the 'leaders' that were used to sustain interest in the Lode and extract assessments for the other mines. The reversals of form were sudden and violent. The MINING AND SCIENTIFIC PRESS made trouble. In June, 1889, it wrote to the title 'What Becomes of the Bullion?' and followed it up under such head-lines as 'The Mines in
the Hands of the Mill-Men." In July, 1890, it reported that the "Hale & Norcross managers are building another reservoir to catch the rich slime that is allowed to escape through their peculiar mode of milling. Our correspondent says that this slime assays from $30 to $40 per ton, which he thinks is very good slime to come out of $20 ore." This mill, being in Carson City, was more accessible to observation than most of the others, which were 20 miles away, on the Carson river. The Mining and Scientific Press further reported that "in the confidence on the 1100-ft. level they are in good ore, assaying $60 per ton, which they are running out through the Yellow Jacket, but of which no further record is kept." In other issues it was pointed out that the Con. California & Virginia and the others, did not sample their ore, as required by law, and that only the mill-men sampled it; that the mills could extract 85 to 90% of the battery-assays, while they returned 65%. and that some mills were steadily working 100 and 200 tons of tailing per day. The trustees were slow to act, but they finally found it necessary to do something to save the trustee machine.

In the spring of 1893 the ore from the Con, California & Virginia averaged $30.46, the battery-assays $27.43, and the bullion returned was $25.98, or 87.4% of the battery-assays. The Nevada mill, which had previously extracted only 30% for the Hale & Norcross, now worked $27 ore for the Potosi, and extracted 79% of the ear-sample and 88.3% of the battery-assy. But the good results arrived too late. As occasionally happens in the land of the free and the home of the brave, the grafters had remained free and brave long enough to get away with nearly everything in sight. The production of the Lode in 1892 had fallen off to two millions, and for the rest of the nineties there was 'very little doing.' Some good ore was found to go below water-level in the Gold Hill, and in 1890, R. F. Morrow formed the Gold Hill Pumping Association. After a year of delay a steam-pump was started in the Crown Point incline. The water was lowered a couple of hundred feet, but the expense was enormous. Charles Hirshfeld, in command of the Bullion and Exchequer, could not collect the assessments, and on the withdrawal of those mines, pumping was stopped.

Morrow and Sharon, in an effort to keep Gold Hill alive (and their mills in business) worked the low-grade 'gold vein' on the foot-wall, beginning in 1891. The ore milled gave assays from $14 downward, and up to the year 1894 considerable quantities were extracted from the richer portions of the gold vein. The ore was milled and concentrated on Flue vans at a charge of $2 per ton, and the railroad made a special rate of 65c. per ton to the Carson river. By piecing out with a liberal levy of assessments, Morrow, Sharon, and others were able to bear up against their fallen fortunes. The trustee system faced hard times in 1893. The Exchequer company took in 66% of its stock on a delinquent assessment; the Alta took in 51%; Hale & Norcross, 23%, and so with others. Then the miners were asked to accept a reduction of wages from $4 to $3 per day; but the miners, being 'wise to' the situation, gave the retort courtone. They told the companies that they would have to reform themselves first. They pointed out that A. C. Hamilton was drawing $2500 per month as superintendent of six mines and the Ward shaft, and was spending most of his time elsewhere than on the Comstock Lode; also that other superintendents were doing likewise. The miners' committee pointed out that the salaries were out of all proportion to the number of men employed. In Alta, for example, not a pick was swinging, but the salary list was $675 per month, and the monthly expense reached $3475; Alpha spent $60 for wages and $375 for salaries; Confidence had one miner, and paid $300 in salaries; Overman spent about as much money for salaries as for miners; and so it went. The managers heat a hasty retreat, lest the miners might give the public further undesirable information. The Comstock may languish, but it is never dead. Just when the public had lost interest, the system again found a leader. Con. California & Virginia, a never-ending wonder, in 1894 found some $80 ore, and cheered the market with a dividend. It takes only one leader on the Comstock to furnish 30 other mines with assessment money. The system survived, but it was not thriving.

In 1898, the Comstock Pumping Association was formed by Charles Hirshfeld, a stockbroker. After many delays the water was lowered in the C. & C. shaft, and as a consequence Con. Virginia (name changed again) found an orebody on the 2050-ft. level that was followed across the line into the Ophir. The latter has been stoping ore continuously since October, 1903. This orebody, which has been producing both shipping and milling ore, is proof positive that the former criticisms by Becker and other writers were warranted; namely, that the lower levels were never properly explored in the eighties, and that there are large areas below the 2000-ft. level that have never been explored at all. In consequence of this success the Ward Shaft Association was formed by the 'middle' mines in 1903, and has now recovered that shaft down to the 2475-ft. station. The work at both these shafts was described by Walter D. O'Brien in the Mining and Scientific Press of June 13, 1908. With the renewal of deep mining in 1903, affairs on the Comstock were slightly revived. Many men who knew the history of that wonderful district again took an interest, and have since been regularly contributing to the assessments. It was represented that the Comstock management had reformed; that there was no more graft; that the companies were now being run honestly in the interests of the stockholders. But the public gradually recovered from this pleasant delusion, and 1908 came in with almost universal expressions of distrust.

It must not be supposed that the Comstock trustee system, fashioned like a political machine, has survived for more than four decades without some assaults upon it. In 1876 there were a number of changes in the directorates. After the report of the Belcher for that year there was an attempt to get the stockholders together, but without success. In 1890, M. W. Fox brought suit against the directors...
of the Hale & Norcross to account for some of the 'very good slime' that had been going through their privately owned mill, and in 1895 he got a judgment. The Mining Stock Association was formed in 1890, ostensibly to combat the 'system.' The stockholders of the Kentuck brought suit against Governor Stevenson of Nevada, who was miling the Kentuck ores, and the Governor compromised. Attempts have been made to amend the laws. In his message to the California legislature in 1877, Governor Irwin said: "There should be legislation to better protect the stockholders in mines from the mismanagement and rascality of the directors. . . . The laws should compel directors to operate mines in the interest of all the stockholders, and not in the interest of an inside ring." In consequence, stockholders got the right to inspect their own mines, which the managers had formerly denied to them; but the 'system' was left intact. In 1880, Senator Felton introduced a bill to make presentation of certificates good for votes at company elections; but it also had the impractical provision that the names of both trustees and trustees must be entered on the books of the company. In 1891, Assemblyman Bert introduced an act to give bona-fide stockholders the right to vote their stock, whether it stood in their own names or in that of the trustees. And in 1905 a law was passed providing that only bona-fide stockholders could vote. This endangered the vote of trustees who did not know who their trustees were; but no advantage was taken of it, and the law was repealed by the next legislature. The only way thus far by which the system has been worsted has been by a group of men buying control. In the last couple of years the Virginia 'system' has thus lost the Best & Belcher, and the Gold Hill 'system' has lost the Yellow Jacket and the Crown Point. The trustees, of course, own no stock. They never would think of paying assessments. When a few stockholders have kicked, the machine has laughed at them; when the machine has been tackled hard, it has pretended to reform. In 1883, the Mining and Scientific Press published an editorial on 'The Top-Heavy System.' "It was a poor way," it said, "to raise $100,000 by assessments, and fritter away $75,000 of it in useless expenditures, the other quarter going to the mine. With the new order of things now going on there is a much better prospect for the mining interests." But the old order, and not the new, was what the stockholders found in existence on the Lode in the spring of 1908.

There were two systems in control: The Gold Hill mines (except the Yellow Jacket) were controlled by R. F. Morrow, of San Francisco, and W. E. Sharon, of Virginia City. It is the same old game, although the plum tree is not as fruitful as of yore. Morrow was in the Gold Hill 'mill-rig' more than a score of years ago. W. E. Sharon is a nephew of the man who was the father of Comstock high finance. The Morrow machine collected $153,234 in assessments in 1907, and kept about a dozen men at work (one shift) underground. That means that only about 10% of the money was spent in miners' wages. The Gold Hill mines did no pumping, and the rest of the money went into general expenses, including salaries. When H. L. Slosson, Jr., took over the Yellow Jacket from the Morrow interests, he made it produce 180 tons per day, instead of nothing, and his salaries amounted to just one-half of what they were under the graft régime. So little was being done by the Morrow machine that one man had time to be foreman of seven mines. The superintendent of these seven mines was of course an honorary office, of the pleasant type evolved under the trustee system.

The Confidence, Challenge, and Imperial are jointly running a drift toward the west outcrop from the bottom of their shaft on the 70-ft. level, not much below the bottom of their dump. They collected nearly $40,000 assessment money in 1907, and are advancing 10 to 11 ft. per week. This means that the gross cost of this drift is $70 per foot; it could be run by contract for $15. The Morrow managers are good fellows, and as jolly entertainers as can be found anywhere, but from the financial standpoint, their mines are bad actors—even for the Comstock.

In the Virginia district the trustee machine was found to be composed entirely of brokers. They did not hold stock persistently. Look on any stock-book for the men who had the smallest number of shares and you identified the board of directors. At the Ophir stockholders' meeting of 1907, 26 shares were represented in person. At the Chollar meeting of 1908, the directors had 31 shares (total market value $3,10) in their own names. It was the same old system. Coherence is given to the Virginia system by means of the Comstock Pumping Association and the Ward Shaft Association, an offshoot of the former. The same men being in control of all the mines (except the Best & Belcher and the Hale & Norcross), they could dip into the different treasuries for pumping expenses as they saw fit, just as though the assessment money of the different mines had all been thrown into a common treasury. For instance, Con. Virginia, and not the pumping association, paid $100,000 for the Riedler pumps, and for many years (up to February, 1907) that mining company also paid for the six men who attended those pumps—because Con. Virginia has a name that can raise money. When Con. Virginia had ore it paid 50% of the Comstock Pumping Association's expenses, and Ophir paid 35%. When Ophir got ore, the figures were reversed. It is evident that the mines must contribute to the expense of pumping, but it is disquieting to the stockholders of one mine to have no written agreement with the other mines, and not to know for how much the trustees may dip into the treasury. Gould & Curry is 2100 ft. nearer to the C. & C. shaft than to the Ward shaft, but it contributes more than half its income to the latter. The fact that Gould & Curry will probably never use the Ward shaft does not seem to occur to its board of directors—as the Ward shaft needs the money. Honorary superintendencies still exist. The State Treasurer of Nevada, D. M. Ryan, is superintendent of the Sierra Nevada, Mexican, Union, Bullion, Alpha, and Exchequer. The Secretary of State, W. G. Douglas, is superintendent of the Gould & Curry, Chollar, Po-
The trustees do not appear to have exercised ordinary business ability in their dealings. In 1899 they had $100,000 on hand with which to obtain electric power. The Riedler pumps (to be installed) required a maximum of 600 hp., and 1000 hp. would fill all the requirements for some years to come. The field was open, and the mines could have built their own power-plant on the Truckee river, and have put up a 26-mile transmission line, from the money they had on hand. But instead of doing that, they gave the $100,000 to the Fleishackers with which to build a plant. Of course, it was pretended that they got the $100,000 back in the form of rebates, but that was mere matter of phraseology. If it is figured that they paid $5.80 per horse-power month on peak load (they now pay $5), then they did not get it back. The advance was $87 per horse-power on the plant installed, and was about enough to build the cheap type of 1500-hp. plant that was constructed. The company is said to have paid a dividend a month after it started. The Fleishackers have since installed 1000 hp. more, and are getting about $100,000 per year out of the stockholders, with more to come. Ophir has been paying for a rock-breaker, and then paying the Kinkead Mining & Milling Co. $2.70 per ton for milling and concentrating. For the last two years it has had enough money in its treasury to build a mill, and enough ore in sight to pay for the mill by the saving in cost of milling. The Kinkead Mining & Milling Co. is said to pay 100% dividends per annum.

There has been no evidence of an appreciation of the relation of fixed cost to total cost of mining or exploration. It does not appear to matter how much money is used for salaries and pumping while the Ward shaft is being put down, or while the Savage, the Hale & Norcross, the Chollar, and Potosi are waiting for transportation in the Sutro Tunnel. It is interesting to note what happened when the Con. Virginia was shut down during the late financial crisis. In his report of November 8, 1908, the superintendent said: "All work in the mine has been suspended." Mining was not resumed until January, 1908. The mine expenses average $13,000 per month; in December less than $4000 per month was cut off, and less than $2500 per month was saved by stopping the mining work that had been going on. During the Company’s fiscal year 1907, more than 81% of the cost was for fixed expense, and less than 19% was for mining work on the 1600, 2250, 2350, and 2450-ft. levels. If we except the 2350-ft. drift, which was run to ventilate the Ophir stopes, then less than 10% of the stockholders’ money was used for actual exploration, other than fixed expenses. One of the noticeable features on the Lode today is the slowness with which the drifts are advanced. In the seventies and eighties it was the exception for a drift to be advanced less than 30 to 40 ft. per week. This refers to average ground and not to drifts like the Chollar-Potosi 3100-ft. level, which was advanced in the black dike on the footwall for week after week at the rate of 80 ft. per week. The best work done recently was in October, 1905, when the Ophir reached the 2200-ft. level by a

tosi, Justice, and Alta. The town clerk also gets on the salary-roll. This is no argument against the gentlemen mentioned, but against the system that employs mining superintendents who do not have to spend all of their time at the work of mining. D. M. Ryan’s work at the Union shaft was excellent, and the plant was spick and span. But the Sierra Nevada, Union, and Mexican collected $120,000 in assessments in 1907, and were employing underground not more than two miners per mine. Instead of spending 50 to 75% of their money for miners’ wages, as other mines that have no smelting charges are able to do, the Union Shaft mines spent about 8%. Ophir was found to be grinding money for pumping expenses and salaries, but with ore that averaged above $30 per ton, and stopes 25 ft. wide, opened on two levels, it was producing only 40 tons per day. On April 18, 1906, it had $50,000 in bank, and at the end of 1907 it had $19,000. For the six months from October, 1907, to March, 1908, inclusive, its average receipts per ton were $25.70, and the expenses were $25.06. Considering the work to be done, its expenses were probably the highest in the world. Gould & Curry collected $32,400 in 1907, contributed $17,500 to the Ward shaft, and absorbed the balance without one miner being at work—in fact, it had not done any mining for many years. Savage had only two or three miners at work (through no fault of its superintendent); likewise the Hale & Norcross; likewise the Chollar and Potosi together. The Julia and the Bullion contributed to the Ward shaft, but the only mining man in sight was W. C.Ralston, secretary. The Alpha and the Exchequer also contributed and did no mining.

The Comstock system is cleverly devised. By giving a man a number of salaries the amount entered on the books of any one company seems small, but the aggregate is much larger than would be paid for the same services in the competitive world. Behind the mines stand the shaft associations and the pumping associations. These spend the money for the mines. For example, the Ophir does not pay its own miners nor purchase its own supplies. A stockholder cannot find out whether his money is being honestly spent except by going through a great multiplicity of accounts. The accounts are not kept after the ordinary manner, and it is impossible to determine what are the different components of the cost of mining except by observation on the ground. For instance, a clerk may be on the salary list, and also gets $40 more salary on the pay-roll. One half of the time of the chief machinist at the C. & C. shaft was charged to compressed-air, not because the compressors had been repaired, but because it was necessary “to charge his pay against something.” As a matter of fact, he had been very busy on other work. The Con. Virginia has been running a drift on the 2350-ft. level to ventilate the Ophir stopes, and has been paying for it at the rate of $60 per foot for labor alone. It is of no use to the Con. Virginia, but the five Ophir directors are all Con. Virginia directors; so they dipped into the Con. Virginia treasury for the coin.
winze that had been sunk 200 ft. through rich ore. The drift from the bottom of the winze was advanced for two weeks at 25 ft. and for three weeks at 30 ft. per week. After that, lethargy set in again. In the Con. Virginia the average progress on the 2250-ft. level during the calendar year 1907 was 15.8 ft. for the 33 weeks that work was being done. The big men of the bonanza days may have been grafters, but there were a few miners among them.

It is only reasonable to suppose, from the few instances related, that the 'commission' system has been pretty generally in vogue as a small draft. It was the custom to purchase supplies in Virginia City without inquiring what the price would be, and the mines paid higher prices than individuals. The powder graft is noticeable, not because of the amount of money abstracted, but because of the fact that no shame seems to be attached to it. Zadig & Co., stock brokers, are agents for the Hercules dynamite at Virginia City. They have formed a combination with the agent of the Giant Powder Co., who is a clerk in the employ of the mining companies of which Mr. Zadig is a director. Mr. Zadig cannot see any reason why he should not be a trustee for numerous stockholders, and a director in numerous mining companies, and should not at the same time charge his trustors 18c. per lb. on 13c. dynamite.

Much of the work of exploration on the Lode appears to be aimlessly done. It is not known today by the mine managers what can be done with the Comstock ores under modern metallurgical treatment, and at what expense. So far as practical work has gone, the firm of Chas. Butters & Co., cyamidizing the Ophir tailing, has a monopoly of the present knowledge. There are some large bodies of lode-grade ore above water-level, but what can be done with these is a question yet to be decided. Not a 'system-controlled' mine on the Lode has a mill of any description. In the work of mining, the Comstock Lode is far behind other districts. For driving and sinking, heavy drills made in Reno are used, though the porphyry does not require them. Light air-hammer drills for stoping, which have proved such a success in other camps, are unknown. The work at the Ward shaft is of great moment to the stockholders who are putting up the coin. More than $550,000 has been expended, but no definite program has been announced. The general opinion is that the work there is being done for the purpose of opening up the ground in the vicinity of that fatal drill-hole on the 2810-ft. level of the Exchequer which flooded Gold Hill in 1882. The only official reports at that time spoke of stringers of low-grade ore having been cut on the 2400 and 2810-ft. levels, but ever since that time dramatic stories have been in circulation to the effect that the drillings assayed high, and that a miner, fleeing before the steaming flood, carried in his hand a piece of bonanza ore. As a journalist, one well known upon the Lode, has remarked: "It is a difference of opinion that gives rise to horse-races." Whether the Ward shaft will proceed to use the big electric pump now being installed, for the benevolent purpose of draining an ocean of water from the Gold Hill mines, which are not contributing to the expense, or whether it will spend some more years in sinking to the 3100-ft. level, of which there is occasional mention, is unknown to the stockholders, although the Ward gets half their assessments. The practice of selling the Comstocks 'short' has had something to do with the laxity of management, and with the failure of the brokers to use their best efforts to make the mines pay. Not every speculator can sell the stocks 'short.' Only the brokers, and those to whom they wish to grant the privilege, can go 'short' of the market. A broker has in his office 10,000 shares of a certain stock, the certificates having been left with him by his customers. He may be holding them awaiting sale at a given price, or he may be holding them for a customer for the convenience of his paying the assessments on them, or he may have advanced money on them, or advanced the money to pay an assessment on them. The broker does with these certificates just as a bank does with its deposits. He figures that all of the 10,000 shares will not be called for at once, and that 5000 shares will meet all probable demands; so at the right time he goes 'short' of the market by selling the other 5000 shares for, say, 30c. per share. He can loan the $1500 thus received to his customers, and charge them good interest on it. The time for the inevitable assessment gradually approaches, and if a 'strike' has not been made in the mine, the price declines. For, without a 'find,' the stock is going to be worth about the same amount after this assessment is paid as it was after the last one was paid. The stock that was worth 30c. has a 10c. assessment levied on it, and slowly declines until on the day the assessment is delinquent it is worth about 20c. The next day, the 10c. assessment having been paid, it sells for 20c. plus 10c., or 30c. again. If the speculator is afraid to stay 'short' of the stock for a long time, because of possible developments, he buys back, when it is 20c., the stock that he sold at 30, and returns the certificates to the broker's office. He has thus made $500 by the transaction. If he stays 'short' of the stock at the time the assessment is delinquent, there are then only 5000 shares in the broker's office, while the customers send the money to pay the assessments on the 10,000 shares of stock deposited with him, being a total of $1000. The broker takes $500 into the office of the mining company, together with the 5000 shares, and has the certificates stamped 'Assessment No. 23, Paid'; and he keeps the other $500 as his profit on the transaction. The people to whom he has sold the other 5000 shares pay the assessment to their brokers or to the mining company direct, and get their certificates stamped "Paid," and the 'short' has no responsibility in that regard. In other words, there are more assessments paid to the brokers and to the mining company direct, than there is stock in existence, by the amount of the stock that has been 'shorted' out of the broker's office. If a man is 'long' of a stock when a dividend is declared, he gets the dividend in cash; if a broker is 'short' of a stock when an assessment is delinquent, he gets the assessment in cash. As a con-
dence game, 'shorting' the Comstocks is without a peer. The brokers on the inside can see to it that certain mines do not strike a bonanza, and as long as the stock does not go up, and force them to cover at an advanced price, there is no possibility of their losing, except through the stock being cornered. The business may seem trivial, but it is the nickels that make the street-cars pay. The Comstock mining companies collected $30,000,000 in assessments in 1907, and the further amount of assessments collected by the 'shorts' must have been no inconsiderable sum. Much of the financial history of the Comstock has been made by the 'shorts,' who have many times been cornered in the earlier days, causing a particular stock to jump hundreds of dollars per share without apparent cause. And then the price would fall again as rapidly as it rose. Some brokers, or their friends, stay permanently 'short' of the stocks for years at a time, just as a bank always has a part of its deposits loaned out. Of course, this system has evoked criticism. In 1877 the Mining and Scientific Press said: "A great deal of attention has been called of late to the custom among brokers of lending stocks not belonging to themselves, but to their customers. In many cases this is prejudicial to the bona-fide owners of the certificates. Now that so much public comment has been made concerning the practice, it is possible that some remedy will be applied." The difference between stockholders and stock-owners is an important one. In all cases in which the brokers act as trustees they are the legal stockholders, because their names are entered on the certificates and on the stock-books of the corporations. The people who have bought the stock-certificates, and who pay the assessments, are the stock-owners; but generally they do not become stockholders, in the sense above stated. They can not vote at the annual elections unless they obtain new certificates, made out in their own names. The majority of the stock-owners are not stockholders, and can not vote, therefore the directors ignore them.

The Comstock system is like a political machine. Every one connected with it is expected to work to get the names of the right men on the certificates as trustees. Then the trustees vote for the right board of directors, and the salaries are dispensed. Next the brokers put out their lines of 'shorts,' and then come the assessments and the profits. A few judicious reports from the system's managers on the Lode, in regard to certain work that is being done in a selected place, will boost the price up; and a few certificates borrowed from the customers' deposits in the brokers' offices will drive it down again. It is an ever revolving cycle. Trustees, salaries, shorts, and assessments. As long as the machine is preserved, and the public will take an interest in the stocks, there is no need to work the mines, as mines. Whenever the public refuses to pay assessments, it is necessary to find some ore and make a 'leader' in order to bring back the crowd. There are many personal antipathies among the brokers. They may have played their little deals against each other, and have had their quarrels; but up to 1908 they have all stood together like henchmen about a political boss in order to preserve the Comstock machine.

In the first few months of 1908 the assessment payers were tired out again. Some of them investigated and grew belligerent. Papers were prepared to take the matter into the courts; but the unexpected happened. Charles Hirshfeld, president of the Comstock Pumping Association and the Ward Shaft Association, also president of a string of Virginia mines, together with B. F. Shaw, another broker, invited certain assessment payers to take an interest in the management and to offer suggestions. Accordingly some new men were installed upon the directorates of the Mexican, Ophir, Con. Virginia, and Exchequer, without waiting for the annual elections. Their suggestions have been acted upon in certain particulars. There is now a committee of three to make purchases of supplies in the open market. Salaries have been cut, both in San Francisco and at Virginia City by all the companies in which Hirshfeld and Shaw are prominent, and the aggregate saving thereby is placed at more than $50,000 per year. It is agreed that each mine that has ore shall accumulate a fund whereby ultimately it can build its own mill: and exploration is now a little more active. But as soon as reform made an entry, all the forces of reaction commenced to gather and to get under steam. Some brokers had strongly objected to the stockowners in the first place. The Gold Hill system would have none of them, and was resolved from the start to hold on to its ancestral perquisites, or to die with its boots on. The old system still controls the boards of directors of the Virginia mines, and the assessment-payers are only in the management on sufferance. If the men who are putting up the money to run the mines take an active interest in affairs, and take over the management of their own properties, then the Comstock is likely to have a genuine revival, and once more to become an important camp. This is true not only from the technical standpoint, but also from the speculator's standpoint, for every important boom in the Comstock that has lasted more than a few days has been based upon actual mining development. But as yet the revival is not assured. There is evidence that the reforms are not being accepted in good faith, and it would be strange if they were. Many brokers are known to have grown wealthy out of the old order of things, while the stockholders have been heavy losers. The Comstock has passed through a long and exciting history, but it has never yet been reformed.

Safety fuse is defined in the Western Australian 'Mines Regulation Act' as a fuse 'which burns and does not explode, which does not contain its own means of ignition, and which is of such strength and construction that in burning it will not communicate laterally with other like fuses. Its rate of burning must not be less than 50 seconds nor more than 100 seconds per yard.'

Butte heads the list of California counties in the production of the precious metals during 1907, the total being $2,795,807.
COMPANY REPORTS.

KERR LAKE MINING COMPANY.

This is an important silver mine at Cobalt, Ontario. The annual report covers the fiscal year ending August 31, 1908. During that period the production amounted to 1,473,712 oz. of silver from 525 tons of ore. The gross value of the product was $757,554; the cost was $139,531, leaving an operating profit of $618,023, and a net profit of $184,826. The average gross value of the ore was $1502 per ton. Four veins yielded ore. The total linear development amounted to 5475 ft. The deepest shaft has reached 325 ft. only. Diamond-drilling was used successfully in prospecting. Dividends aggregated $500,000 during the year. Benjamin B. Lawrence, of New York, is the consulting engineer and S. R. Henkes is manager.

TOMBOY GOLD MINES.

The Tomboy is a famous mine situated in Savage basin, near Telluride, Colorado. The mill and mine are both on the edge of timber-line, at 12,000 ft. above sea-level. The original mine, to exploit which this company was formed, proved a disappointment; when the Tomboy 'petered out,' the manager, John Herron, obtained an option for his company on the adjoining claims, that now constitute the Argentine mine. By aid of the Argentine, the Tomboy was resuscitated and again ranked as a productive gold mine.

The report covers operations for the year ending June 30, 1908. During that period the mill treated 104,091 tons of ore, from which $999,021 of bullion was obtained, at a total cost for mining and milling, of $543,506, so that the final profit was $444,515. Adding sundry rents and royalties, the total revenue was $1,012,502. The cost of mining and development was $3,27; of milling, $1,28; and of general expense, 57 cents. Thus the total expenditure was $5,133 per ton. Ore reserves are estimated at 410,000 tons, of which 58,000 tons is already broken in the stopes. During the year the addition of ore reserves kept pace with the extraction. The deepest level is at 2100 ft. below the outcrop. Two dividends were paid in the 12 months; these absorbed $90,000. The capital of the company is $500,000. This is one of the successful undertakings controlled by the Exploration Company, of London. D. A. Herron is manager. He is a brother of John Herron. It is pleasing to note that the accounts record a bonus of 1½% on the profits for 1907 paid to John Herron, in recognition of his loyal service to the company. An honorarium of £500 was also paid to the present manager of the mine.

ALLIS-CHALMERS COMPANY.

The total earnings for the year ending June 30, 1908, after deducting cost of manufacturing and selling, taxes, insurance, and other general expenses, dividends on preferred stock outstanding of the Bullock Electric Manufacturing Co., and ordinary provision for doubtful accounts, were $2,573,960.93.

Loss:

Expenditures for maintenance, repairs and renewals on buildings, machinery, plant, tools, etc. $778,476.64
Reserves for depreciation on buildings, machinery, plant, tools, etc. 313,778.60
Interest on bonds and notes payable $605,891.45
Special reserve 60,000.00

Net earnings for the year . $ 615,314.24

Inasmuch as, owing to present financial conditions, there may possibly be a shrinkage in the collection of certain bills receivable, it has been deemed advisable, out of abundant caution, to set aside out of the profits, on this account, the special reserve of $60,000 shown above. Beginning with the second quarter and continuing for half of the fiscal year, owing to the severe contraction in general business throughout the country, the volume of the Company’s sales averaged about one-half of normal. During the last quarter there was a gradual and steady increase in orders booked.

MEXICO MINES OF EL ORO.

This is a young mine adjoining the Esperanza at El Oro, Mexico. It is under the same control and management as the El Oro Mining & Railway Co. Fergus L. Allan is superintendent; R. M. Raymond is general manager. The mine is capitalized for $185,000. A 40-stamp mill and cyanide plant was completed on October 1, 1907. During the ensuant mine months of the ending year (1908) there was crushed 62,394 tons, yielding bullion worth $507,971, or an average of $12.95 per ton. The extraction of gold and silver averaged 84.4%, but the metal in solutions and precipitation boxes brings the total estimated saving to 59.6%. The total cost of mining and milling was $6.53 per ton. In addition, 2035 tons of high-grade ore, was shipped to smelters, yielding a net profit of $75,656, or $126.74 per ton. The total receipts were $227,096, and the resulting profit, after deduction of all expenses, local and at London, amounted to $132,096. Ore reserves are estimated at 205,310 tons containing $11.72 in gold and 6.8 oz. silver per ton. The main shaft is down to the sixth level, but sinking has been resumed recently. The cost of mining is $2.36; of development, $.35; of mill, $.56; of cyanidation, $1.52; of general expense, $.14; the total is $6.32. The total tonnage was 64,432, and the total profit $94,665. This is an exemplary mining company.

NIGEL GOLD, TRANSVAAL.

The Nigel Gold Mining Co., Ltd., a company incorporated in Natal and operating on the Rand, at its twentieth anniversary, held its annual shareholders’ meeting for the year of 1908. Out of this dividends absorbing $655,931 have been paid. The Transvaal profits’ tax amounted to £550; extraordinary capital expenditure redemption, £5081; depreciation written off, £13,746. The mill crushed and treated during the year ended June 30 last 121,830 tons, and following the established policy of the company, development was carried on actively, adding 170,055 tons to the ore reserves. This represents the result from 7093 ft. of drifts, 1075 of raises, 786 of winzes, and 290 of cross-cuts. The total ore-reserves developed to date aggregate 491,073 tons, of which 214,073 assay above 8 dwt. per ton, and the remainder slightly less. The mill contains 55 stamp works, which averaged an effective run of 3415 dwt. per day, the per diem stamp-duty being 5.481 tons. The ore milled averaged 3.518 dwt. per ton, from which a recovery by amalgamation of 4.465 dwt. per ton was effected. The pulp entering the cyanide plant was separated into 77,314 tons sand, and 44,117 tons slime, assaying respectively 4.795 and 5.376 dwt. The theoretical and actual extractions from the sand were 57.044 and 94.398%, respectively, and from the slime 84.09% and 84.56%. The costs were .

THE HERMANE & DOLTHOFF MFG. & SUPPLY CO., Denver, in its October announcement, calls particular attention to the new line of small Corlis engines, of Murray Iron Works manufacture. It carries the 10 by 18 size in stock, and lays stress on its efficiency and small steam consumption. The new double tang drill socket is also described, this being a new device, made by the Cleveland Twist Drill Co., which allows a complete renewal of a drill which might otherwise be considered useless.
Decisions Relating to Mining.

Specially reported for the Minining and Scientific Press.

Abandonment of Mining Claim—Re-location.

An actual abandonment of possession by a locator of a mining claim, such as would work an abandonment of any other easement, would terminate all the right of possession which the locator then had, and the ground embraced in such mining location would become a part of the public domain, and render it subject to another location before the expiration of the statutory period for performing annual labor.

Laubert's Lien on Mining Claim.

The Alaska Mining Code providing a lien to laborers for work done on a mine at the instance of the owner or his agent, was held sufficient to give a lien on the interest of the owner of a mining claim for improvements made thereon under the directions of a lessee, with the owner's knowledge, and in the absence of any disclaimer of responsibility by him. And in an action to foreclose such lien in such case, the lessee is not a necessary party.

Cascaden v. Wimbish, 161 Fed. 241, April, '98.

Fraudulent Sale of Mining Stock.

The owner of mining stock induced a third person to purchase by fraudulently representing that the stock purchased was to be treasury stock; but instead of treasury stock he transferred to the purchaser his own private stock. In an action for damages, it was held that, inasmuch as treasury stock under any circumstances is worth neither more nor less than any other stock, the damages were wholly speculative, and there could be no recovery. The Court intimated that if the purchaser had acted promptly he might have rescinded the sale, re-issued the shares, and recovered the purchase money from the person to whom he paid it.

Location of Mining Claims—Overlaps.

A mining company located a claim, and thereafter on the same day located another claim, the latter overlapping a part of the former. The various acts requisite to a valid location were first performed on the claim first located, and subsequently on the claim last located. Under such circumstances the first location constituted the senior location, and the overlapped, that is, the disputed territory, was a part of such first claim, and was thereby segregated from the public domain. On the abandonment of such first location, by reason of the failure to perform the annual assessment work, such overlapped territory did not become a part of such second claim, but reverted to the public domain, and was subject to re-location. Thereafter a third person located a claim which included such conflict-territory, and took the necessary steps for a valid location. In a contest as to the right to such overlapped territory the person making the last location had the title to such conflict-territory.

Moorehead v. Erie Mining & Milling Co., (Colo.) 96 Pac. 253, June, '98.

Mining Claim—Performing Location Work.

The purchaser of a mining claim did no work thereon except the digging of a hole to show his claim of possession, and for the purpose of erecting a drilling machine, and not as a mining exploration; he did not take a drilling machine on the premises for more than a year after the digging of such hole, but guarded the claim to prevent others from entering thereon for the purpose of location. In the meantime a third person entered upon the land and made a valid discovery and location, and as against this discovery and location the original purchaser was not in such actual possession of the land as to entitle him to the claim as against such third person.

Guggenheim Operations.

Some unfortunate investments of the Guggenheim interests in the mining line are just coming to light, and explain in a measure why there has been such a house-cleaning in the field forces, for the purchase of these properties was largely upon the recommendation of the highest paid mining engineering talent in the country. The Guggenheim Exploration Co., which is the principal mine owner of the Guggenheim outfit, has expended a total of $27,000,000 in acquiring properties within a comparatively few years.

One of the leading mining assets of the Company was the property at Velardeña, Mexico. This was a silver-lead group, and was operated privately for years by Barton Sewall and associates, known as the American Smelting & Refining crowd. The property produced between $8,000,000 and $10,000,000 from the old silver-lead ground from carbonate ores. Then no zinc had appeared in the ores, and smelting costs were exceedingly low, and it was possible at that time to derive excessively large profits in treatment of custom ores. The Sewall interests sold the properties to the Guggenheims for $6,000,000, and they expended $1,000,000 in a new furnace plant and $400,000 on a new power plant. At the same time they purchased a copper property, 16 miles distant, and built a railroad to connect it with the Velardeña plant, so that the total investment at this point amounted to not far from $10,000,000. Soon after the Guggenheim control, however, arsenic came in the ores, and operating conditions changed so that it is now said that there has not been a dollar of profit derived to date on this investment. At the copper mine they went down 600 ft. and found that the ore is practically exhausted, running at the lower levels but 1½% copper. Here is a $10,000,000 investment which could probably not be re-sold for over one-tenth of the cost. Velardeña is now a fighting word in the Guggenheim office.

A second pronounced Guggenheim failure was a silver-lead property near Silverton, Colorado, for which $2,500,000 was paid for the mine, and an additional $750,000 expended in a new mill and equipment, only to discover, when the mill was ready to operate, that the mine was practically out of ore.

The Guggenheims likewise have a $7,000,000 investment in the Yukon, but the public was given an opportunity to help shoulder this burden. The selling of the shares was given to Lawson, who was given an option upon 700,000 shares at $5 per share. The Yukon flotation—some people call it by a harsher name—resulted in 400,000 shares of the company being distributed to the public at from $6 to $8 per share. The distributor got his stock for $5 per share net, but as he had previous to the public offering distributed 300,000 shares among a favored few at 5½, he was obliged to take this stock back in the open market at from $6 to $8, so that the net Lawson profit was 5% of a point on the 400,000 shares, or $270,000. The Guggenheims paid the advertising bills of about $80,000, and received an acknowledgment in the shape of an immense bunch of Lawson pink's sent to the Mauretania when Daniel Guggenheim sailed for Europe shortly after the offering.

Another chapter could be written of the Guggenheim investment for the American Smelting Securities Co. of between $8,000,000 and $10,000,000 in the three smelting plants on the Pacific Coast. These included the Tacoma plant, for which $4,000,000 was paid, or many times the price at which the same plant had been offered to other interests six months previous to the time the Guggenheims purchased it. The Solby plant on San Francisco Bay, paid almost as much as the Tacoma plant. It is not now productive of earnings, because it is shut down tight, the agricultural interests having secured a permanent injunction against its operation because of the smelter fumes. A third was the San Bruno plant, which was to have been built on San Francisco Bay, at a cost of $7,000,000, but was abandoned after an expenditure of $1,500,000 because of court injunctions from the agricultural interests.—Boston News Bureau.
MINING AND METALLURGICAL PATENTS.
Specially reported for the MINING AND SCIENTIFIC PRESS.

In a magnetic ore separator, the combination of a main support, a shaft journaled therein and depending therefrom, supporting rods also depending from said main support and arranged about said shaft, a head fixed upon the lower end of the shaft to rotate therewith, a series of electro magnets carried by said head, brushes carried by the head and in electrical connection with the magnets, an annular commutator inclosing the shaft above the head for co-operation with the brushes and provided with a gap adapted to be crossed by the brushes, said commutator having arcuate openings through which said supporting rods extend, whereby the commutator is adjustable circumferentially on the rods to vary the position of the gap, means for securing the commutator to the rods in adjusted position, and electrical conductors for connecting the commutator with a source of electrical energy.

The method of reducing ore which consists in heating a mass thereof to a high temperature without melting it, then subjecting the heated mass, under confinement, to contact with fresh hydro-carbon fuel, distilling the fuel by the heat of the ore and thereby generating a deoxidizing atmosphere to react upon the ore and reduce metallic oxides to metal.

In an ore separator, an inclined trough including longitudinally disposed air flues, and a plurality of transverse hollow flues upon the plate connected with the said flues, the said flues having air outlets in one of their sides.

Apparatus for treating ore-pulp, comprising a tank, means for circulating and aerating material therein, means for the circulating material, a plurality of filter cells in position to be submerged in the material in said tank, and means for withdrawing liquid from the tank through said cells.

In a chute, the combination with a chute proper, having side walls and a bottom section, of ways positioned interiorly on said walls, angle irons positioned exteriorly on said walls forming a bracing thereof and a vertical extension for said ways, a chute section extending away from said ways provided with an opening in its bottom portion in line with said ways, a gate slidably mounted in said ways, a link pivotally connected with said gate, a lever pivotally engaging said link, and independent means for supporting said lever.

The method described, which consists in subjecting within a furnace structure a body of ignited sulphide ore to the action of a flux and an oxidizing atmosphere, and the oxidized body derived therefrom to the action of a reducing atmosphere of high temperature.
Publications Received.

There is a perennial need for brief treatises on metallurgy to afford a ready means for non-technical readers to become familiar with the outlines of modern methods. Since the publication of Horns' excellent little manual, some twelve or fifteen years ago, the field has remained uninvaded by any other brief treatise conceived in the scientific spirit. It is admitting a high degree of excellence to say that Mr. Wysox has given us a work that will rank in the same order, with the advantage of being up to date. This is a difficult achievement for any technical book, which is usually out of date as soon as printed. So swiftly does technology change that Mr. Wysox has suffered in like manner, no mention being made of the application of the cyanide process to silver ores, which method is fast driving out every other, except in the cases of argentiferous copper and lead ores. The book is particularly strong in its treatment of fuels, and in the metallurgy of iron and steel, as would be expected in a work by an assistant professor in Lafayette College. In these departments it is certainly informing and modern, giving facts which all iron and steel users should know. The book should appeal to a large class of readers, and would be excellent as a syllabus for a course of college lectures.

The peculiar function of this book is to provide in convenient form a complete review of all the elements entering into the problem of installing and efficiently operating a modern steam-plant. It is not exhaustive in regard to any one of the many subjects treated, but it gives practical data and working formulas, so that it constitutes a handbook sufficient to enable one to cope effectively with difficulties as they arise, even though further data be unavailable. An excellent discussion of feed and blow and condensate is given, which deals elaborately with coal and fuel-oil, and with such substances as peat, wood, straw, saw-dust, and bagasse. The presentation of methods for the use of fuel oil is particularly commendable. Boilers are treated in some detail, with special reference to selection and maintenance. Methods of smoke-prevention, involving a description of leading types of mechanical stokers, constitute an interesting chapter. Other subjects treated are superheated steam and superheaters, coal and ash-handling apparatus: chimneys, their design, construction, and efficiency; mechanical draft, condensers, water-feed purifiers and heaters, pumps, separators and traps, piping and fittings, lubrication, testing, and so forth. The discussion of the turbine engine is quite full and interesting, but the reciprocating engine is disposed of more summarily. The general treatment of data on the steam engine is sufficient excuse for the brief treatment given. The book excels in the exposition of the accessories to a steam-power-plant, which are discussed in a way that will prove particularly useful to those engineers who have to grapple only occasionally with steam-power problems. The explanation of the steam indicator and the interpretation of indicator-drawings is the apparatus and methods for dynamometer tests, is especially concise and clear. Simplicity and clarity of statement characterize the book throughout, and it is full of the facts that the practical worker needs. It is handsomely printed and profusely illustrated with detail drawings. Every steam-user's library should contain a copy.

Records With the Wood Drill.

In driving a 2000-ft. tunnel, 7 by 12 ft., in the Pine Brook mines of the Scranton Coal Co., at Scranton, Pa., two 3-in. Wood drills were used. These drills have a stroke of 6½ in. and will drill to a depth of from 10 to 14 ft. The drills were worked in 8-hr. shifts. The average depth of hole driven by each machine in one shift was 127 ft., thus drilling nearly 10 ft. per hour. The tunnel was through the hardest rock encountered in mining in these coal fields. Although the work was severe, the cost of maintaining the drills was small. For the two drills the total amount spent for repairs and renewals was $15.95, the details being: two feed screws with nuts complete, 12 sets of piston packing, 6 sets of piston ring springs, 5 dos. ratchet springs, and 2 joint plates for the pistons in any well made drill that wear out under ordinary conditions. This gives a cost for maintaining one No. 3 drill of about $8 for the drilling done in the excavation of about 3100 cu. yd. of rock, the number of feet drilled per cubic yard excavated being more than in open-cut work. The No. 3 Wood drills do excellent work in shaft-sinking in what is termed 'blocky ground.' The Scranton Coal Co. mines some coal from veins that are from 2½ to 3 ft. thick. It is necessary to blow the roof down or take up the bottom. This work was formerly done by hand, and in 8 hr. two men seldom drilled more than 2 ft. in the roof. Now the company uses No. 2½ Wood drills, with two men to each drill. These move from room to room as they are needed, and drill from 60 to 75 ft. of hole in 8 hours.

Commercial Paragraphs.

The California One Testing Works is in receipt of a consignment of ore from the Nevada Wonder, at Wonder, Nevada, with a view to making a complete test as to best metallurgical treatment.

The Butters Filter Co., San Francisco, advises that it has recently closed a contract for the installation of a 90-leaf Butters filter at the Jesus Maria mill of the Guanajuato Amalgamated Mines Co., at La Luz, Mexico.

The Cleveland Rock Drill Co. has been incorporated as a subsidiary company to the Cleveland Pneumatic Tool Co., and will handle the business of the mining department, which has greatly increased since the parent company entered the rock-drill field.

Daniel Best, for many years at the head of the Best Manufacturing Co., of San Leandro, California, has retired in favor of his son, L. C. Best, who has been elected president of the company. The Best traction engines are well known in almost every part of the world.

Catalogues Received.

The Allis-Chalmers Co., Milwaukee, will be glad to send its Bulletin No. 1433, called 'Prospecting Mills for Free Gold Ores,' to anyone who is interested.

The Jeffrey Mfg. Co., Columbus, Ohio, has published, under date of September, 1908, its Bulletin No. 27, descriptive of coal washing plants and equipments.

The W. S. Rockwell Co., New York, has recently issued a small folder showing its crucible melting furnace, in which either oil or gas may be used as fuel.

The Keystone Driller Co., Beaver Falls, Pa., are distributing catalogue No. 7, which is a description of the new gasoline drilling machines now put on the market by that well known firm.

The Maginnis Galvanized Steel Flame Co. has recently issued, through its sales agent, T. C. Egleston, Denver, Colorado, an elaborately illustrated description of galvanized steel flumes for irrigation, power, and mining canals.

The Ames Engineering Co., New York, has recently published Catalogue No. 4, which is a complete description of the different pebble mills handled by the firm. With it is distributed a small folder on modern mining machinery.
EDITORIAL.

According to a published statement of the postmaster of New York, the two-cent rate of postage, which went into effect on October 1, has already doubled the volume of foreign mail transmitted from, and to, New York.

Referring to a question of correct usage in addressing a fellow citizen of this great Republic, we rise to inquire whether it was proper for the agent of the Standard Oil Company, when enclosing a check for $10,000 to the Attorney General or general attorney of the State of Pennsylvania, to address that gentleman as "General" and "Honorable".

At Bendigo, in the Australian State of Victoria, the Victoria Reef Quartz Company has found gold-bearing ore at a depth of 4504 feet, in a winze sunk from the 4254-foot level. Native gold is plainly visible, associated with iron pyrite. Apparently the ore forms part of the cap of a saddle reef and it will be necessary to sink the main shaft—now 4300 feet deep—in order to extract this ore profitably. The Australian Mining Standard claims this to be the deepest discovery of gold-quartz ore in the world and we believe the claim justified.

Railroad Building in northwestern Canada is likely to develop new mineral regions. The line from North Bay to Temiskaming and thence to James Bay, at the southern end of Hudson Bay, will aid the exploration of the northern portions of the province of Quebec and Ontario. The Grand Trunk & Pacific will have a branch to the west end of Hudson Bay and will cross the Rocky Mountains in reaching to Port Simpson, on the Pacific coast. The United States Steel Company has put prospectors along the surveyed route of this new trans-continental railroad; during the summer they have been about Lake Nipigon and the adjacent country. There exists a spacious wilderness in this part of the American continent and it has mineral possibilities. New mining developments are likely to be heralded from this quarter.

Quotations of $5 and 10 cents for Greene Gold-Silver Company stock, coupled with the practical retirement from business of the man whose name was given to this, and to other enterprises in Sonora, accentuate the fact that W. C. Greene has run the gamut of prospector, promoter, and financier. The Colonel's withdrawal from New York to Cananea and his ill health are coincident with the practical collapse of enterprises undertaken four years ago in a spirit of flamboyant recklessness. It is no new story. The man who is an energetic and
successful prospector, the pioneer of frontier enterprise, and a mining adventurer—giving the word its old and romantic significance—is apt to become an ill-regulated and irresponsible promoter when he gets into the hands of the gentry who live by the exploitation of the simple and greedy. The explorer is rarely a business man and the prospector is rarely a successful promoter.

OUR CORRESPONDENT at Guadalajara mentions the fact that the Amparo Mining Company has contracted for the planting of half a million eucalyptus trees. This plantation will, in a few years, furnish timber for use underground. We commend this provident enterprise. It should prove profitable. Similar plantations in South Africa and California have furnished valuable material for mines.

REVIVAL OF INTEREST in gold dredging is manifest in several directions. Some of the evidence indicates honest industry, some of it suggests spoofery. In the September issue of The Review of Reviews, of London, there are several pages of drivel concerning the "gold ship," "the sands of Ptolemais," "the modern El Dorado," and so forth; these glittering phrases, like the lights on a child's Christmas tree, being hung about a so-called "character sketch" of "a popular speaker, a campaign orator," and a promoter who "has added to his other activities the Apostolate of the Gold Dredge." It is bald-erdash of a superlative kind, a write-up of a most meritorious character, and proof that The Review of Reviews has become a second-class periodical; but the expense involved in this dishonest form of advertisement indicates the belief that there is a public interest in dredging. That is the only significance of the article.

APPRECIATION of stocks since the culmination of the panic, twelve months ago, has progressed so far that in railroad shares it reaches from 10 to 75 per cent, and in industrials from 40 to 160 per cent of the quotations at that date. This is about the time when the powerful speculators in control of the market let go their stocks to the public, which is now being fed with optimistic statements concerning industrial activity and financial recovery. Such statements are, fortunately, largely true, but the prices of stocks have discounted the fact already. We shall see the old and familiar game of a stock boom in the course of which the public will buy from the big operators the shares purchased during the days of panic; then will come another reaction, and the schemers on Wall Street will buy back to sell again when another boom comes, and so on. History repeats itself.

THE PROSTITUTION of journalism in the interest of stock-jobbery was illustrated in a typical way by recent proceedings in the Bay Street Police Court, before whose historic bar moral delinquency has been brought to account time out of mind. The defendant was described as "the editor of a financial newspaper called The Critic. He was also the proprietor of a Stock Exchange speculative agency called The Critic Agency, which was conducted by him in connection with The Critic newspaper. He was the sole director of three syndicates and two companies distinguished by the name of 'Common Weal.'" Later, the prosecutor said that "The Critic, newspaper, of which the defendant was the editor-in-chief, posed as the champion of investors, the champion of honest criticism in the public press, and the opponent of dishonest persons connected with company promotions. On the heading was a quotation: 'I am nothing if not critical.' . . . It was quite clear that the defendant posed as the champion of the investing public at the time he was now alleged to have been defrauding them." In short, it was one of very many pseudo-literary squibs whose motto should be: "I am nothing if not a blackmailer." Usually such papers are nothing, and when they are anything it is only because some people are ignorant and others are afraid. Owing to the vast and varied character of the financial activities in motion within the boundaries of the City of London there is plenty of scope for papers of The Critic class. One of them is, or was (for we do not know whether it exists any longer) the Anglo-Colorado Mining & Milling Guide, a pitiful little sheet that undertakes, or undertook, to give advice to investors when not engaged in blacking the boots of one man or blackening the character of another.

Justice and Law.

It has been said that morality is a matter of latitude, although doubt may well exist concerning any coincidence of isothermal and isomoral curves. Curves are inherently immoral if a straight line be accepted as the symbol of rectitude. But these verbal sinuosities should not be followed to their limit, for they end in a maze. They are prompted by reading, in The Australian Mining Standard, an account of the proceedings in the Federal High Court sitting at Melbourne on September 17. A mining company had brought suit against a broker for "the sum of $500, and the value of 320 shares in the company, on the ground that, being a promoter of the company's flotation, the defendant had received these as commission, or profit, without disclosing that fact to the directors and shareholders." His Honour found that "defendant was bona fide a promoter of the company from first to last, and that the amounts had been illegally and secretly obtained." We quote our contemporary. His Honour proceeded to make some severe remarks on the transaction: "The defendant says that such bribing of directors is a 'custom' in forming mining companies. This is a startling avowal with regard to a leading Australian industry, especially as coming from the president of one of the chief exchanges. But if the practice of bribery is so rife in the promotion of mining companies it is well to have it made public: and if it is my unpleasant duty to expose, as far as the evidence allows me, what has been done in this case, and to say that in no circumstances can such a 'custom' be treated as legitimate. This is not a
court of morals, but it is a court of justice according to law; and as such it condemns both the giver and the taker of a bribe." "A Daniel come to judgment," indeed; we salute Mr. Justice Higgins and congratulate a community that is served by such a man.

To a dweller in San Francisco this plain statement is as a drink of cool clear water in a dust storm. Here by the Golden Gate they spin fine distinctions between the giver and the taker of bribes; they do the same at New York, St. Louis, and Philadelphia. Evidently human nature is made out of the same frail substance at Melbourne as in San Francisco, but the strong judge, able to administer "justice according to law," is scarce in both localities. We set law without justice and we get justice without law. Civilized government rests on the closest possible interpretation of one in terms of the other; lacking such interpretation, we have anarchy.

Investment and Speculation.

Our friend The Canadian Mining Journal, takes exception to some recent remarks appearing in these columns in which the speculative feature of mining was emphasized. Other contemporaries have objected to this emphasis, recognizing in the word "speculation" something malign as compared to the dignified term "investment." It is largely a matter of usage. People have fallen into the way of using "investment" for ventures that are really speculative, and "speculation" has been fouled by the vagaries of irresponsible adventurers until it is a word of ill omen. Let us return to correct definitions. No discussion is profitable unless preceded by agreement as to the meaning of the terms employed. Even dictionaries are not inerrant, for they are the work of human beings. Thus the Century says that "investment" is "a placing or conversion of capital in a way intended to secure income or profit from its employment." This is badly expressed; the one valuable idea is the connotation of income as a sign of investment. The Standard says that it is "laying out money productively, especially in a permanent manner." A manner cannot be permanent; as well fossilize an adverb or petrify an attitude while releasing the actor. But here we get the idea of productivity, that is, the placing of money so that it shall yield an income. The further suggestion is made that such money shall remain thus placed for a long period; the element of time is introduced. This is correct. However safe and sound the use made of money, it is not regarded as an "investment" if it is to be withdrawn next day. Thus we arrive at the definition of "investment" as the placing of money for a period in the expectation of a regular income therefrom. No reference is made to enhancement of the principal, it is the dividend that attracts: the safety of the principal is assumed. We shall see that in "speculation" the position is reversed, the enhancement of the principal becoming the chief factor, while the question of a regular income is subordinated.

The Century defines "speculation" as "the investing of money at a risk of loss on the chance of unusual gain." The only objection to this otherwise excellent definition is that it defines one word in terms of the other one with which we are contrasting it, so that the presence of "investing" is undesirable in a definition intended to distinguish between "investment" and "speculation." Turning to the Standard, we find that "speculation" is "a more or less risky investment of money in expectation of considerable gain." The "more or less" is idle, and "investment" is open to the objection already made. Both dictionaries recognize risk as an essential and both connote the "gain" with the "risk." We venture to define "speculation" as the placing of money in a risky venture in the expectation of unusual gain. The expectation involves an increase of the principal and usually disregards the yield from dividends, the latter being important rather for the effect of enhancing the value of the principal than for their own sake. A test between an "investment" and a "speculation" is the willingness to take the papers that stand for them and put them in a safe for a term of years. Men "lock up" an investment but they hold a speculation ready for quick realization. Thus British consols and United States bonds are "locked up," only to be removed temporarily at regular intervals when a coupon is to be detached; the owner does not buy them in the expectation of a big rise in the quotation, he values them mainly because they yield a regular and absolutely assured income. Thus also with a few of the best railroad bonds and even with the debentures of some mining companies. But it is possible to speculate even in bonds; there are brokers and others who buy and sell bonds for the sake of the fluctuation in the market price rather than for the dividend, which may not change. The investment of one man becomes the speculation of another; the one buys to hold and to win an income; the other buys expecting to sell at an enhanced price, before a dividend becomes due. On the other hand, a speculation may gain in stability so that the conditions favor a regular income without disquieting fluctuation in the amount of the principal, until finally the money involved returns a regular yield, while the quotation remains steady; then the purchase or holding of that stock becomes based more on its yield as an investment than on its enhancement as a speculation. The shares of a few mines belong to this category, although most mines are essentially speculative. The Canadian editor quotes farming and building construction as forms of industry that are speculative. They are; some of them. Any use of money can be made speculative by taking risk in the expectation of unusual gain. "No industry is free from the effects of human errors," says the gentleman at Toronto. That is true, nor is it disgraceful to err, save to make the same blunder in the same way twice. "Mining should be a business in the strictest sense of the word," but this assumes that speculation is divorced from business. That is incorrect; business and speculation were married long ago; they are indissolubly bound. Mining is one of the best of the businesses in which man engages, and it is speculative because the risk involved is compensated by unusual gain.
**Personal.**

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

**AleH H. Rogers is in Chile.**

F. W. Bradley is at Elk City, Idaho.

J. R. Finlay has returned to New York.

Charles Butter has returned from Mexico.

Scott Turner left Nome for Seattle on October 22.

Martin Schwerin, of New York, is in San Francisco.

E. A. Weinberg was recently at Concurrency, Queensland.

F. C. Alsop, of Gloce, Arizona, is in San Francisco this week.

Theodore Douglas was married at Greenwich on October 7.

O. H. Packer is examining copper mines at Yerington, Nevada.

T. L. Carter is expected in San Francisco about November 1.

J. Power Hutchins arrived in San Francisco this week, from Idaho.

George Jamieson has returned to Seattle from southern California and Nevada.

Zelma Lane is returning to Australia, after a ten months' stay in California.

H. Parent Julian has returned from Mexico and will be going to London soon.

Lane C. Gilliam spent the season in Alaska and has returned to Los Angeles.

W. B. Lamb, of Lamb, Wainwright & Co., Los Angeles, is in British Columbia.

Belmont Bush returned from Mexico this week and has gone to Warder, Idaho.

Olive R. Finn has been examining the Gold Reef mine, near Phillipsburg, Montana.

F. I. Johnston is at Santa Barbara, Cal., and will go shortly to northern Mexico.

George J. Bancroft announces the removal of his office to 222 McPhee Bldg., Denver.

H. E. T. Hallifax has been appointed associate professor of mining in Toronto University.

E. M. Hamilton was married in England recently and is expected in San Francisco shortly.

E. H. Garthwaite has returned to Oakland from the examination of mines in Sinaloa, Mexico.

Henry Leigh Hunt passed through San Francisco, on his way from Warder, Idaho, to Sonora, Mexico.

**Obituary.**

Henry Augustus Butter died at Berkeley, California, on October 26. He was born at Haverhill, Mass., 58 years ago. Acute congestion of the lungs proved fatal, after a brief illness. He came to California at the age of 14, and after attending the old College of California he was employed by Bancroft & Co. In 1878 he went to Leadville, Colorado, and engaged in mining, gaining experience that proved invaluable. In 1891 he went to South Africa, and became the successful promoter of an urban electrical tramway system at Johannesburg. Gaining the support of Wernher, Bell & Co., he was able to organize syndicates for the successful installation of tramways in Switzerland, Mexico, and South America. Thus he became rich. In 1895 he returned to Oakland, where he had a beautiful home. He organized the Northern Electric Co. and became heavily involved after the San Florida disaster. This depleted his fortune and caused domestic troubles which clouded the last years of his life. He is survived by his brother Charles, by a wife, a boy of 15, and several step-children. His sudden death has evoked many expressions of regret and esteem.

ARIZONA.

COCHISE COUNTY.

The shaft on the Warren property has reached a depth of 815 ft. and is still in dry close-grained limestone carrying considerable iron stain. The shaft is perfectly dry and shows no indication of water. The group is east of the town of Warren.

PIMA COUNTY.

The management of the Helvetia has decided to ship its sulphide ores to custom smelters rather than to remodel the old smelter. Accordingly shipments have been started to the Old Dominion, at Globe, and will continue at the rate of 100 tons per day.

SANTA CRUZ COUNTY.

The Pittsburg camp, in the Santa Rita mountains now looks very much like a mining camp. The boiler, hoist, pump, and air-compressor are all in place and in operation. The shaft has been timbered and sinking has been resumed after a delay caused by waiting for the machinery. The shaft is about 90 ft. deep and going down at a rate of four feet per day. About 20 men are employed.

YAVAPAI COUNTY.

(Special Correspondence.)—The old Vulture mine, which has recently passed into new hands, is employing about 30 men at work improving roads and repairing the buildings, in preparation for the further opening up of the mine and starting the mill. The boilers and many of the machinery for the new electric power plant have arrived. The plant is being erected on the grounds of J. B. Holland, onequarter of a mile east of Wickenburg. The new plant, which will supply power to mines in the surrounding country and furnish lights for Wickenburg, will cost more than $250,000, and will generate from 1500 to 2000 h.p.—A 40-stamp mill will be installed at the Monarch mine, near Wickenburg, to take the place of the 10-stamp mill now in operation on the property, and a great deal of work is going on in the way of development. James Platt is the manager of this promising property.—Thomas Crook and partner are working a group of claims 12 miles south of Wickenburg, and have a considerable amount of low-grade gold ore on the dump holding for the resumption of work at the Humboldt smelter. They are down 128 ft. on one claim and on another 75 ft.—T. W. Wampler, representing a syndicate of Los Angeles men, has purchased the Peterson group of mines in the Weaver district. The property is immediately northeast of that belonging to the Octave Mining Co., at Octave, and comprises seven patented and six unpatented claims. The veins, which are extensions of those on the Octave group, are opened by a 712-ft. adit. It is practically certain that a 10-stamp mill will be in operation on the property within six months. W. L. Coffin, of Prescott, has been appointed superintendent.

CALIFORNIA.

BUTTE COUNTY.

The Blue Channel Mining Co., composed of Los Angeles men, has purchased 240 acres of ground near Paradise, which includes the old Durgen drift mine, and has placed Edward D. Kesterline in charge of the work. The gold-bearing channel lies between a lava cap-rock and serpentinite bedrock and is claims to be 40 ft. thick, running $5 per yard.

NEVADA COUNTY.

(Special Correspondence.)—The Grass Valley Dana Mining Co., composed of Tonopah capitalists, has taken a bond on the Christopher Columbus and Dana claims and started a force of men at work. A two-compartment shaft will be sunk and considerable machinery installed. The claims are between the Idaho-Maryland and Golden Gate mines.—The Tell Mining Co. is repairing its storage reservoir and making other preparations for the working of the Blue Point placer during the coming winter.—Owing to the following of the late storm by sharp north winds and warm days the water problem is fast becoming as serious as earlier in the season. Many of the mines that resumed operations immediately following the storm are expecting to cease work in a few days unless conditions change.—A rich shoot of ore has been struck in the Lecompton. The mine is being worked under a bond by A. M. Gilbert, of Santa Barbara.—T. and J. Williams have leased the Benallack claims, between the Brunswick and Union Hill mines, and are prospecting for considerable work.

Graa Valley, October 25.

SAN BERNARDINO COUNTY.

A syndicate of Goldfield mining men has purchased from William C. Laey, H. C. Emert, and H. J. West a group of
three claims in the Old Woman mountains, about 40 miles southwest of Hart. The consideration is $15,000, a portion of which sum was paid down, and the remainder comes due on November 15. A force of six men has been started to work and a number of good stringers have been cut.—A vertical shaft has been opened in the property of Millbank Johnson, known as the Sundown. It is said that a hoist and compressor will be purchased in the near future. The adit on the same claim is in 200 ft. and has exposed a body of low-grade ore averaging about $7 per ton.—The Hart Florence has found $165 ore in its shaft at a depth of 139 ft. A cross-cut has been started at the 186-ft. level and will be run 100 ft. before drills to the east and west are started. A hoist will be put in and the shaft sunk to the 400-ft. level. J. C. Popper is manager.—The Flyer shaft is being deepened and the material taken out is being sent to the Little Giant mill. A depth of 50 ft. will be attained before cross-cutting or stoping is started.

**SHASTA COUNTY.**

F. H. Russell, of Redding, and his brother have found the rich gold channel known as the Tom White one-half mile south of Igo. The property was purchased last April after a number of years’ dispute as to the ownership. It now appears that the adit was made some time ago, but have delayed announcing it until they could make all payments and so secure absolute possession. It is understood that several offers have been made, but that the owners are holding for $100,000.—The first furnace of the Balaklala smelter at Corinn was finally blown in on October 21. The plant has a capacity of 1500 tons per day and is said to be the best equipped on the Coast. The Mammoth smelter has five furnaces, but their capacity is not so large as the three modern ones of the Balaklala. This is the fifth copper smelter to operate in Shasta county.—Paul Smith, of Kennett, has bought from Chris Baust an undivided half interest in the Golden Dream mining claim east of the Sacramento river above Kennett, adjoining the old Trask place. Joseph Sambor, of Corinn, owns the remaining half interest.

**SIEIRA COUNTY.**

The management of the White Bear mine has started a raise from the No. 1 adit to strike the gravel recently found in the drift above. This plan is necessitated because of the great amount of water which was found in sinning on the bedrock above.—The force at the Indian Hill mine has been increased and the work on the dam is being pushed. J. B. Elsea is superintendent.—Thomas Mason is doing the assessment work on the Golden Rooster gravel mine, near Bunker Hill.

**TOLOUMNE COUNTY.**

Operations have been started at the Draper mine, where a few men are at work under the superintendency of R. A. Nichells.—Work was interrupted last week at the Confidence mine due to a shortage of water.—The shaft of the Anzonda, near Columbia, has reached a depth of 150 ft. and the water is coming in such quantities that pumps are to be installed. Two veins have recently been cut.

**COLORADO.**

**CLEAR CREEK COUNTY.**

(Special Correspondence.)—It is expected that during the early part of the coming month the Lincoln adit will reach the Virginia City vein, cutting it at the 500-ft. level of the shaft workings. Driving has been started on the blind vein recently intersected and a 4-ft. streak of ore is being followed that carries gold as high as $500 per ton. As far as the ground has been opened the streak has been found to be continuous. W. C. Hood is manager.—A new strike is reported from the Black Eagle mine on Chicago Mtn. in running the east drift and the University adit has widened to 7 ft., about 12 ft. of which is high-grade ore containing more than $50, while the rest is worth from $30 to $55 per ton. This property is operated by the Honest John M. M. & T. Co., J. F. Puchert serving as manager.—A large party of stockholders in the Golden Glory T. M. Co. spent the week in camp. All were from Ft. Worth, Texas, and while here arrangements were made whereby enlarged development will follow. A. A. Hayden, of Denver, is manager.—While work has been curtailed to a considerable extent at the American Siskins mine during the last six weeks, J. J. White, who is manager, is making ready for extensive development. Machine drills will be brought into use on the 160 and 275-ft. levels of the Headlight shaft workings. In the east drift of the 275-ft. level a streak of smelting ore is exposed that is 18 In. wide and from recent shipments returns as high as 600 oz. silver have been received.—The Miller adit, on Saxon Mtn., has reached another vein. On the foot-wall there is showing a streak of heavy lead ore that is 4 In. wide. Tests show 44 oz. per ton in silver and lead.—The Allen property, in the gulch between Griffith and Alpine Mtn., is again undergoing development. J. Raymond, the owner, is driving the adit forward and is following an 8-in. streak of silver-lead ore worth $20 per ton. The heading is now nearing a cross vein and the objective should be reached in 15 ft.

W. Parraghe has taken a lease on a block of ground on the Hancock level of the Sunburst, on Democrat Mtn. Driving has been started and a streak of ore is being followed that is from 6 to 10 in. wide. The ore is worth from $90 to $90 per ton in silver and lead.—M. J. Riley, leasing on the Grant level of the same mine, is sending out occasional shipments of 226-oz. silver ore. No effort is being made for a heavy production. Mr. Riley being satisfied with operating expenses, pending an advance in the price of silver and lead.—A new shaft is about to be started at the operating the Mendota mill, sent out a carload of zinc last week. The shipment was consigned to the Canon City smelter and carried 60% zinc. The mill has a capacity of 60 tons per day and is being run on three 8-hour shifts. Dump matter is being treated exclusively.—Work is now in full swing on the Josephine mine, Kelso Mtn. Shipments will be started within the next two weeks. Frank Book, who is superintendent, expects to reach the second level of ore within the next six months. Adolph Nelson is manager.—The Cumberland mine, at Alice, is again undergoing development. The water is being lifted from the shaft, preparatory to lengthening the drifts. A. V. Dickinson, of Alice, is manager.—A bonanza strike was made a few days ago on the second level of the Santiago mine. A body of ore has been found that is 5 ft. wide and the first shipment brought a settlement of $48 per ton in gold, silver, and copper. Stoping has been started and from this time forward regular shipments will be made. In the breast of the west drift a streak of heavy lead ore is exposed that is from 4 to 6 in. wide. Harper & Richards are operating under lease.—Shipsments have been started from the Wilcox adit, the ore being taken from the ground on the Paymaster vein, being operated by the Waldorf Metals Company, Georgetown, October 24.

**LAKE COUNTY.**

It is announced that all the iron-silver properties in the Leadville district will be operated as soon as the various plants are completely equipped with electricity. The work is being done by the Leadville L. & P. Co. and the power will come from the local plant at the mouth of the Yak adit. The hoist of the South Moyer is already equipped with electricity.—The Gypsy Mines Co. has been incorporated at Leadville to work the Gypsy property on the lower and Derry adit. The incorporators are W. T. Collins, H. B. Collins, E. W. Collins, M. A. Hoyt, and James C. Crawford.—The annual meeting of the New Monarch Mining Co. was held in Leadville last week and the old board of directors was re-elected. A number of directors from Cleveland inspected the property and have decided...
to sink the Cleveland shaft 100 ft. deeper and also to add other improvements. These same men are also interested in the Salida smelter and inspected that plant on the same trip.——The new owners of the Hilltop mine, in the Horse-shoe district, are preparing to actively operate that property. J. C. F. Berger will be manager and associated with him in its management is a large group of owners, of which he is the chief.——It is reported that the Clark interests in the Greenback mine have been sold to a party of Boston capitalists, and that this famous bonanza property will again be operated. It is understood that Patrick Mulrooney is instrumental in negotiating this transaction, and that he is anxious to resume work on the property. Under the reported arrangements of affairs the ores are to go to an independent smelter.

TELLER COUNTY.

The notion of the Portland Gold Mining Co. to amend its complaint, in the suit brought against Stratton's Independeace, and lessees of that corporation, to recover heavy damages for ore alleged to have been wrongfully extracted from within the boundaries of the Portland estate, was denied by Judge Lewis in the United States District Court at Cripple Creek last week.——The new owners of the Hilltop mine, in the Horse-shoe district, are preparing to actively operate that property. J. C. F. Berger will be manager and associated with him in its management is a large group of owners, of which he is the chief.——It is reported that the Clark interests in the Greenback mine have been sold to a party of Boston capitalists, and that this famous bonanza property will again be operated. It is understood that Patrick Mulrooney is instrumental in negotiating this transaction, and that he is anxious to resume work on the property. Under the reported arrangements of affairs the ores are to go to an independent smelter.

IDAH0.

SHOSHONE COUNTY.——The Hecla Mining Co., at Burke, has declared its regular monthly dividend, which is at the rate of 2¢ per share and involves the distribution of $20,000. This is the sixty-fourth dividend paid by the Company, making a total distribution of $1,560,000, of which $140,000 has been paid this year.——The Snowstorm Mining Co., at Mullan, has paid its first dividend for the year. This is at the rate of 3¢ per share and involves the distribution of $45,000. It is understood that arrangements have been completed by which the Company will receive a reduction of $1 per ton on its freight rate, and in view of the fact that shipments amount to between 400 and 500 tons per day, the monthly saving on this alone will be considerable. The Greenough Bros., who control the mine, also control the Panhandle smelter, and it is thought that a good deal of the ore from the mine will in the future be sent there for treatment.——William Sites, Thomas McIwown, Jesse Freeman, and others, of Wallace, are said to be promoting a scheme for a power line from the State Creek district of the St. Joe river to the Cœur d'Alene.——A letter to the stockholders of the Charles Dickens M. & M. Co. has been issued by H. W. Winfree, attorney for the company. Some time ago suits to the extent of $100,000 were started against the Company, and there has been a considerable amount of dissatisfaction among the shareholders on this account. Mr. Winfree invites all those who are interested in the Company's affairs to call at his office and make an inspection of the books and to satisfy themselves as to the manner in which the indebtedness has been incurred.—Preparations are being made for a resumption of work at the Keating mine in the town of Wardner. David Goodsell, the owner of the property, has arrived in the district and has engaged a force of men to complete the assessment work on the un patented claims of the company. The mine is tied up in litigation, but it is expected that a settlement will be reached in the near future.——A vein 40 ft. wide carrying 2 ft. of shipping copper ore and 28 ft. of concentrating ore has been opened up in the property of the Prudent group of claims on Toboggan gulch about five miles east of Murray. Shipments will commence as soon as the track of the Northern railroad has been completed. James L. Ford & Co., at Cascade, acting on behalf of a number of New York capitalists, has taken an option on 55¢ of the capital stock of the Tarbox Mining Co., whose property is in the Saltesse district. The option is for the period of 69 days and involves about $150,000. A force of men will be started at once on the property, and if the showing is up to present expectations, a concentrator will be built and regular shipments of large bodies of low-grade ore, with some shipping ore, have been opened up, and the property is regarded as one of the best concentrating propositions in the district.——A strike of about one foot of rich copper ore and some good milling ore has been made on the property of the Liberty company in the Lookout district. Comparatively little work has yet been done on this prospect, which is owned by J. H. Potlson, Ed. Werkmeister, and E. C. Fred, of Walla Walla.——J. J. E. Kiermeyer and associates, who are leasing on Colorado King, made a shipment last week. A new ore-house has been completed and the stopes are now in shape to make a regular production.——The Jolly Tar mine, within the corporate limits of Victor, owned by the Strong Gold Mining Co., under lease to Abe Flachs and associates, of Victor, has resumed shipments. Operating between the 290 and 150-ft. points, a large body of ore has been opened up, and the initial shipment last week is estimated to be worth about $15 per ton.——The famous Victor mine, on the northeastern slope of Bull cliff, has been leased to the Western Investment Co. of Victor, Fred V. Bodfish, who was manager of the mine for several years, is confident that the Victor will in a comparatively short time be brought back to the shipping list.

MICHIGAN.

HOUGHTON COUNTY.——The Tamarack Mining Co. is experimenting upon a sub-shaft in its vertical shaft No. 3 in an endeavor to lessen the tremendous haul from the bottom of this opening. The sub-shaft will be sunk at a point 700 ft. north of the main shaft and will go down on an incline parallel to the lode. A hoist will be installed at the collar of this opening and the ore will be trammed from there to the main opening, where it will be hoisted to the surface. By this method it is hoped to save a haul of over 7000 ft. upon the tonnage. This will mean a great saving, as it will be possible to supplant the present heavy duty ropes for lighter ones, which could handle the loads from the less depth as easily as did the others. The hoisting is at present from the seventeenth level. The shaft lacks 10 ft. of being one mile deep, and is the deepest vertical opening in the Lake Superior district.——Ahneeck
is now in ore at its new double shaft, which is 1300 ft. from the Mohawk No. 5 shaft. The Company does not own the outcrop at this point, and in order to develop its property in sections 28 and 29 they have started a six-compartment shaft. As depth is attained the compartments will diverge, forming two shafts of three compartments each. The shafts are now down 70 ft. and are sinking in the hanging wall. As soon as the lode is penetrated the shaft will enter the foot-wall and continue down in it. The shafts are being sunk at an angle of 10° and will strike the lode at a depth of 1250 ft. —No. 1 shaft of the Allouez Mining Co. is now below the twelfth level. The openings here present a much better ground than has been found previously in other No. 1 or No. 2 shaft. The Company is pumping work on the openings and leaving the opened territory, thus accumulating blocks of rich stoping ground that will keep the mine forces busy for some time. No. 2 shaft has reached the tenth level and the cutting of the station has commenced. It is expected that the shaft will reach the lode at a depth of 2200 ft., while No. 1 will strike it on the third level at a depth of 1200 ft. The mine is now shipping about 600 tons monthly, with a total extraction of 15 lb. per ton. —The Atlantic shaft is rapidly approaching the eighteenth level. Stoping is in progress in the twelfth level and driving is being pushed in the thirteenth. The lode opened in the fifteenth level is showing up extremely rich and proves the dip to be north at an angle of 65°. —Concrete foundations for two new steeple compound heads are being put in the Allouez-Centennial mill. The mill now has two simple compound and one steeple compound, which, with the addition of the two new heads and the steeple compound of the two simple heads, will make a battery of five compounds with room for another whenever the production warrants it. The jigs in service in this mill are of the Woodbury type and are giving satisfaction. The Company is having built in the Nordburg shops of Milwaukee a 600-hp. Corliss engine to drive the stamp-mill machinery. When installed this engine will be the largest of its kind in operation at any of the Lake Superior mills.

Houghton, October 24.

Missouri.

Newton County.

(Special Correspondence).—The past few weeks has noted a much increased activity in the Granby field. Perhaps the most important fact from this camp is the record-breaking turn-in made from the Goade mine. A carload of zinc-blende was sold by this company which assayed the highest of any ore in the Granby camp, running at 64.46%. This company has a tonnage mill and makes one from two to three hundred tons a week. The property is on the Little Boss Mining Co.'s ground, where two other mills are being built. The ore is found at 55 ft. and shows a face 20 ft. high and 22 ft. wide. The ground is hard and requires no timbering. Five drill-rigs are actively at work upon the Trent & Granby lands, south of Granby. The first drill strike was made at 250 ft., cutting sheet ore. The latest report of this mine is promising. The Company has a tonnage mill and makes one from two to three hundred tons a week. The property is on the Little Boss Mining Co.'s ground, where two other mills are being built. on their persons and a number of sacks were also taken from the cabins of the guilty men. The offenders are held under bond pending the action of the district attorney, in whose hands the case has been put.

OREGON.

JACKSON COUNTY.

(Special Correspondence).—The Pacific Coal Co., of which R. E. Dean, of Los Angeles, is the largest stockholder, has 2000 acres of coal land five miles east of Medford, on which 4000 ft. of development work has been done. The longest drift goes in 1000 ft. on the vein, the latter being 10 to 12 ft. thick. Mr. Dean states that 75% of the coal thus opened is a marketable commodity. The better quality of it contains 55% fixed carbon, 6% ash, 3% water, and the rest volatile combustibles; the average of fixed carbon is said to be 40%. The Company has steel rails at Medford sufficient for five miles of railroad track and it is probable that a road will be built to the mine.

Champion Bros. have been dredging four years on Foot's creek, near Gold Hill, and have worked out an area half a mile long 500 ft. wide and 35 ft. deep. The ground has yielded 20e. to $1.25 per cubic yard. Their new dredge is of modern design, operated by electric power.

—The Border mine, near Gold Hill, operated by the Connor Water Co., has been active several years, and is opened by six levels from 300 to 1000 ft. long on the strike of the vein, which stands between scheist walls. This Company bought the mine a few years ago and has paid for it from the proceeds of operations. The 10-stamp mill, with plates and tables, is running. Gold hill, which originally yielded phenomenally rich pockets of free gold, the most of which was extracted from 1858 to 1890, is still being worked over on a small scale by individual miners. The black-well hills, on the south side of Rogue river, covering an area of 2 by 6 miles, yielded rich ore in pockets in the early days and are still of interest to the old time miner. The Millionaire mine, in these hills, has a hoist over a 400-ft. shaft, which is worked over and Nissen two stamp mill, with plates and table, which will run this winter. J. T. Davison is in charge.—The Shamrock, managed by W. P. Chisholm, of Gold Hill, has a vein of chalcopyrite ore in a schist country, opened by 1500 ft. of work. The ore will average 3 to 4% copper. —The Corporal G, on Sardine creek, has ore that yields $50 to $70 per ton at the Lucky Bart mill. W. A. Pierson, superintendent of the Black Eagle, is developing and erecting a small mill. The property belongs to Portland people.

Gold Hill, October 10.

MEXICO.

JALISCO.

(Special Correspondence).—The old Matarena mine near Jolapa, in the Mascota district of Jalisco, has been purchased from the Mexican owner by the Matarena Mining & Development Co., of Spokane, Washington. It is stated that the price named in the contract is $50,000, and that a portion of that amount has been paid. T. P. Harsh, manager for the Company, is now at the property. According to the mining history of this part of Mexico, the Matarena mine produced several millions during Spanish colonial days. At the opening of the struggle for Mexican independence it was the scene of a massacre of the Spaniards connected with it. For many years the mine remained idle and the walls of many of the old workings caved in.—M. P. Wright, of Los Angeles, California, representing Los Angeles and Tucson interests, has closed a deal for the Certuenea mines near Ahecutan, in the territory of Tepic. The mines have been extensively developed and are equipped with a small mill. It is the intention of the new owners to at once erect a modern reduction plant, consisting of stamps, concentrators, and cyanide annex. The plans include the installation of a hydro-electric plant at a point five miles from the mines, and the transmission of power for mining and milling operations. The mines are but a few miles from the line of the Southern Pacific extension.—The San Pedro Alamo Mining Co., a Spanish concern of Guadalajara, has decided to install a cyanide plant at the San Pedro Alamo silver mines in the Hostotiyaguillo district and treat the ores by direct cyanidation. The Company is now treating its ores by the old patio process of amalgamation.

Guadalajara, October 20.

SONORA.

(Special Correspondence).—The Quintera mine, in the Alamos district, Sonora, owned by the Bank of Paris, France, is producing an average of 60 tons of ore per day. The metal contents are silver-lead in the upper zones and silver-copper below the 500-ft. level. The mine is operated to a depth of 1600 ft., being the deepest in Sonora. Ninety per cent of the ore is sent to the stamp-mill for concentration, and the remaining 15%, with the concentrate, is reduced in the company's smelter. Good results and clean work are attained.—The San Diogemo mine above the Quintera on the north. The greatest depth attained is 500 ft. on the vein, which at this level is opened for a length of 700 ft., and cross-cuts prove the vein to average 40 ft. wide in the deepest levels attained. The ore to the 250-ft. level is silver-lead. Below that level it changes to silver-copper. The lead occurs as a sulphide and the copper as a glance and chalcopyrite. The mine is owned by the Sonora Central Mines Co. of Chicago. This Company has about completed two years of active development of the vein below the antiqua workings and will soon begin building a modern ore-dressing plant. The product of one foot width of ore on the foot-wall of the vein amounts to 270 oz. silver per ton, the ore being a silver-copper glance. Seven feet of mixed silver glance and chlorides in the centre of the vein yields 70 oz. silver per ton.—The Pulpito mine, belonging to Sr. Gooycoolea, of Alamos, joins the Santo Domingo on the west. A cross-cut adit, 10 by 10 ft. in section and 800 ft. long, cross-cuts a vein 100 ft. wide, the ore being of a mixed smelting and concentrating character.—The Zambona mine joins the Santo Domingo on the north. R. R. Coleman, of Los Angeles, is president of the company. This mine has large reserves of silver-lead and silver-copper ore blocked out to a depth of 700 ft.; also a large tonnage of tailing impounded from former mill work. Building of a modern ore-dressing plant is being considered by this company. All these mines have been operated for 150 to 175 years. Their combined production of silver under the ancient operations was probably 120,000,000 oz. Alamos, October 22.

LONDON.

Lancaster Gold Mining Co. of West Australia.—Troubles of Dundee-

The additional capital of £26,000 raised in April last by the re-construction of the Lancaster Gold Mining Co., operating in West Australia, has proved to be insufficient for any purpose of putting the mine and plant into order, and the shareholders have accepted a plan of raising a further £20,000 by means of preference shares. This mine was floated in London three years ago by Bewick, Moreing & Co., and it appeared to be a very promising low-grade proposition. At first a stamp-mill and cyanide plant performed exceedingly well. Unfortunately the nature of the ore changed considerably as development proceeded, becoming much harder, and the sulphides proving more refractory. It was found necessary to alter the plant to dry crushing, roasting, and cyaniding, and subsequently the plant had to be increased to make up for the greater time occupied in treating the ore. It was thought that an additional £26,000 would be sufficient. This expectation has not been fulfilled. There are several reasons for success not having as yet been attained. The refractoriness of the ore is one, and another is the large amount of moisture in the ore, which necessitates great expense in drying. Also the mine is not sufficiently developed ahead of the mill. At the meeting of the shareholders held this week to consider the state of the Company's affairs the directors and the managers were necessarily in an apologetic mood, and some hot shots of criticism were fired at them. Resolution was moved to the effect that Bewick, Moreing & Co. should retire from the management and let somebody else have a chance, and J. H. Curle spoke of the present miserable condition of the Company being due to the want of development of the mine. Eventually the shareholders decided to persevere on the present lines, and accepted Mr. Moreing's proposition for raising further funds. The present capital in ordinary shares is £250,000 in £1 shares. Mr. Moreing's proposal was to create 100,000 new shares of 1½ each, entitling the holders to a return of 100% out of the first available profits, and thereafter to a preferential dividend of 20%, together with a pro rata distribution with the ordinary shares. Of these shares 6,666 are to be issued now, and a call given on the remainder at £1 each.

A few weeks ago I referred to the serious position of the Dundee-Iron Ore Co. that owns the concentrating de-
posit in Norway. At that time the directors were asking shareholders to subscribe for £100,000 pre-preference shares, in order to provide funds for modifying the machinery with a view to minimising the dust troubles. It is not to be wondered at that the response to this issue has been small. Only about £23,000 has been applied for. It was therefore necessary to place the matter in the hands of the deben-
ture holders, and Mr. Peat and Mr. Dexter, accountants, were made receivers. There are certain further financial complications still to arrange for, in the shape of loans that were issued on the security of prior lien debentures. The Consolidated Gold Fields of South Africa, Ltd., are large shareholders, and they are holders of options for loans ranking with the prior lien debentures. These trustees and ex-directors are now discussing other schemes for re-arranging the capital and providing further funds. It is remarkable how uninviting the Consolidated Gold Fields of South Africa are when investigating their money in mining enterprises outside of South Africa. No statement has ever been made as to the reserves of iron ore at the Com-
pany's property. There are not wanting doubting Thomases who question the extent of the orebodies and who think that this will be a stumbling block in addition to the other drawbacks of high cost, difficulties of briquetting, and the trouble with dust. Before additional money is spent fur- ther investigation of the ore-reserves should be made.

The report of the El Oro Mining & Railway Co. for the year ended June 30 last shows a profit of £205,266, out of which £24,000 has been provided for expenditure on capital account, and £167,062 distributed as dividends. The issued capital of the Company has been increased during the year by £97,500 in shares, paid for the adjoining Somera company under the circumstances detailed by the Mining and Scientific Press six months ago, and now stands at £1,147,500. The total sum distributed in di-

Johannesburg, Transvaal.

Big Consolidation.—Machine Stopping.—Tin Enterprises.—East Rand Shalt Sinking.—Profit Aggregates.

The consolidation of the Village Deep and the Turf mines has been accomplished, all serious opposition having been withdrawn owing to force of circumstances and aided by the special report of Mr. Curtis. Though Rand amalgama-
tions may in time be carried to excess, the consolida-
tion of these two adjoining mines, one producing, but sad-
died with a heavy debt, the other only shaft sinking, but well in funds, has been prompted by the soundest business policy. The capacity of the Village Deep mill is being rapidly increased to 41,000 tons monthly. The Turf mine's seven-compartment shaft will be down to the reef early next year and the two inclines of the Village Deep are being sunk to the level of the assumed strike.

At a meeting of the Chemical & Metallurgical Society the other day, Mr. Johnson, a thoroughly practical mining man who recently advanced daring ideas for 'improve-
ment' in our underground work, replied to his critics. A wide range of subjects has been covered in the discussion, a contention of foremost importance appearing to be that shafts are not worked to proper advantage, and that the standard of assumed shaft requirements is usually exces-
sive. A suggestion was put forward by Mr. Johnson that we should set many more machine-drills to each stop face than practice now sanctions, and thus work out the blocks of a stope quickly, leaving to a few men the job of cleaning up for a given tonnage. A critic urged that the employment of two or three contractors of varying capabilities in one stope would soon bring the face into hopeless shape. To this argument Mr. Johnson replied that he would shift his contractors (as a contractor in hand-stopping does his boys) so as to give the good men the difficult places and the poor men the easy. It is not certain how the good men would fall in with such an arrangement, nor how a contract could be regulated to suit them, if called upon to frequently leave work-places broken to their fancy, and to take up what they might consider a disordered place elsewhere. After all, the capable miner does look ahead, with beneficial re-
sults to himself and to the company, if his contract is favor-
able. Mr. Johnson, in his plea for the greater crowding of stopes with machines, put forward for a parallel development of every works department, and cited the case of operations adopted, the heavy stamps and large mills erected to treat the ore at the utmost speed. It seems that this parallel may lead to a pretty fallacy, for the stope (in length and in width) is more or less a constant, to which the num-
ber of drills must be regulated. Obviously, a stamp does as much work in a 100 as in a 400 head mill. In average Rand stopes more machines than three to 290 or 250 ft. of backs would undoubtedly cause unsatisfactory congestion, and although Mr. Johnson's scheme of mere rapid exhaus-
tion of mine sections is good in principle, its practical adoption presents some serious objections.

Tin continues to be the most popular and promising of
the base metals sought after by the prospecting syndicate in various parts of South Africa. Though a higher degree of concentration in certain places might be advantageous economically, its wide distribution is otherwise a satisfactory feature. During the past week, a new Swaziland alluvial tin deposit has been found under the aegis of influential men. This venture is capitalized at £125,000, and the development of certain of Wright’s concessions will be undertaken, where alluvial deposits have already been proved in the region of the Swazi tin mines and of the McCreedy properties. An effort is now also being made to float a tin enterprise in the Keiberg district, 10 miles from Cape Town, whence lies a number of rich deposits which have been prospected. The reporting engineer suggests the erection of a 10 stamp battery. This concern, called the Tygerberg Tin Mining Co., is capitalized at £90,000 in £1 shares, of which £4,000 are offered to the public. In the usual way, prospective profits are flaunted in the advertisements with pseudo-science, with a presentation of reports of rich assays seductive to the man in the street, and quite meaningless to anyone endeavoring to arrive at the actual facts. Every clerk or bartender in the country knows that an unpayable tin lode may give, upon occasion, a 70% assay. It is much to be hoped that the Tygerberg promoters hold a safe property, for the Cape has had a sorrowful experience in the collapse of the Kulis river tin mines, near the Capital, and another failure would constitute a serious blow to local mining enterprises.

Still another tin proposition has been brought prominently forward by the report upon the Transvaal Bishop Ltd. (in the Waterberg district, north of Pretoria), by Dr. Jorissen and Mr. Hoffman. On this property the mineral occurs both in a lode and in alluvium. It is stated that crushed zones are found between the red granite and the overlying felsite and granophyre, in which pegmatite dikes, leading to tin bearing veins are abundant. A shaft, 100 ft. deep, of this ground is said to be so rich it could be economically sacked and shipped without previous concentration. The most important deposit, however, appears to be the alluvium, of which over 3,000,000 cu. yd. are declared to contain tin to the value of $1 per yard. Hydraulicking is recommended. The water requirements are estimated at 1000 gal. per yard. This will have to be pumped to an elevated reservoir, for this part of the Transvaal is unfortunately not blessed with facilities for gravity water supply as is Swaziland. The costs of working on a basis of 650 cu. yd. per day are estimated as follows:

<table>
<thead>
<tr>
<th>Description</th>
<th>Cost</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pumping, at 3d. per 1000 gal.</td>
<td>£205</td>
</tr>
<tr>
<td>Supervision and labor</td>
<td>475</td>
</tr>
<tr>
<td>Tools, bags, and stores</td>
<td>38</td>
</tr>
<tr>
<td>Smelting charges in Europe, at £1 per ton</td>
<td>250</td>
</tr>
<tr>
<td>Rail freight, at 3d. per ton</td>
<td>59 sq.</td>
</tr>
<tr>
<td>Transport to railway</td>
<td>17 10s.</td>
</tr>
<tr>
<td><strong>Total</strong></td>
<td>£1075</td>
</tr>
</tbody>
</table>

Allowing £25 for contingencies, this works out at 4.3d. per cubic yard, a high figure compared with the records of more favored fields, but one which will allow a good profit if the valuations arrived at are reliable. The outside world, which has had a laugh at the Transvaal over the noisy and despicable flask of the Bushveld, is inclined to receive with a grain of salt all reports concerning tin deposits in South Africa; but it must be understood that the costly lessons of the past have not been wasted, and that a payable industry is being surely established.

Though tin is undoubtedly receiving most attention, silver lead is also enjoying some favor. It is reported that the Transvaal silver mines, closed down (so far as company operations) some 15 years ago, are shortly to be resuscitated by men with large financial resources. The deposits contain copper, silver, and lead, in the form, principally, of galena and tetrahedrite, and occur in the Pretoria series of shales and quartzites not many miles from the Capital.

Another move has been made in the 'far east' Rand toward the wider activity already predicted. This is seen in the renewal of shaft-sinking operations by the Cloverfield Mines, Ltd. In 1906 work in the shaft was suspended, as at many other points along the Rand at this time of depression. A depth of 1345 ft. was reached before closing. The reef has been tapped on this property at depths of 1904 and 2997 ft. by the diamond drill.

The monthly profits of the Rand now exceed £1,000,000. Their rapid growth is shown by the declarations for certain recent periods:

<table>
<thead>
<tr>
<th>Month</th>
<th>Tons milled</th>
<th>Profit</th>
</tr>
</thead>
<tbody>
<tr>
<td>August 1906</td>
<td>874,185</td>
<td>£657,200</td>
</tr>
<tr>
<td>August 1906</td>
<td>1,268,595</td>
<td>724,573</td>
</tr>
<tr>
<td>August 1907</td>
<td>3,157,789</td>
<td>575,927</td>
</tr>
<tr>
<td>July 1908</td>
<td>1,623,591</td>
<td>1,923,236</td>
</tr>
</tbody>
</table>

From these figures it will be noted that in spite of the enormously increased tonnage, occasioned largely by milling more low-grade ore, the profit per ton milled has only fallen in four years an average of one cent per month.

**GUADALAJARA, MEXICO.**

Los Reyes Mines.—Marcus Daly Estate Investing in Hostotipaquillo.—

Railroad Connection to Mazaianillo.—Mines Sold in Ayutla.

Negotiations between representatives of the Marcus Daly Estate, of Butte, Mont., and New York, and the Los Reyes Mining Co., of Guadalajara, for the transfer of the Los Reyes mines, in the San Sebastian district of Jalisco, have been dropped. What is generally regarded as a generous offer by the Daly estate was refused by the local Mexican company, and there is little prospect of the negotiations being renewed. The proposition of the Dales interests provided for a year's development work, in which time they were to spend not less than $100,000, and open unexplored portions of the Los Reyes properties. At the end of the year, in the event the mines developed satisfactorily, the purchase was to be made for $1,000,000. The Daly people are now devoting attention to the Hostotipaquillo district of Jalisco, and it is probable that they will invest there. Henry E. Crawford, of New York, is the principal representative here. The Mazaianillo extension of the Mexican Central Railway, from Tuzapan to the Pacific port of Manzanillo, a distance of 100 miles, is rapidly nearing completion, and will be opened to traffic in November. This line will provide the first connection from central Mexico to the Pacific Coast. The completed line will represent a cost of $20,000,000, or an average of $200,000 per mile. Some of the heaviest railroad construction in Mexico was done between Tuzapan and Colima, where the line crosses the bor-
opinion and determined not to present the objectionable article to Congress. The native press seems to be both for and against the action of the Cabinet, but some are most bitter in their denunciation of the backsliding tactics of the administration. In fact it appears that more criticism has been hurled at the President during the last few months than has ever been directed against him. The sending of a copy of Article 144, the responsibility of mining companies for accidents not due to its own negligence is also removed, and Congress has voted to keep machinery on the free list.

In several parts of the territory of Tepic considerable activity is manifest. The Cambio Gold Mining Co., of Cienfuegnati, has completed at its Bihuanda district, a 35-ton concentrator and is expected to complete a cyanide plant before the end of the year.

In Sonora, the Kansai Copper Co., with a capital of $10,000,000, has been organized by Bissell and Chicago capital for the merging of the Ortega (or Southern), the Red Cloud Copper Co. (or the Consolidated Gold & Copper Co.), and the Miller. El Tigre is said to have been taken by New York capital for $800,000.

In Zacatecas several rich gold finds are reported from the San Carlos mines in Mezquital de Oro. The Masupil Copper Co. is putting in its third tram on the Roe system, and the one connecting the mine with the mill at Concepcion del Oro, a distance of 7 kilometres (or 4/5 miles), whereby, at the rate of 23 tons per hour, the ore is being transferred at 1c. per ton. Work has been started on a 100-ton cyanide plant for the El Tigre Mining Co., of Zacatecas, and is to be completed by the end of the year.

Reports from Nueve Leon are to the effect that the Empire Zinc Co. has bought the Piñadosa mine and dump near Fierro station, Coahuila, and that the Pablo de los Santos has bought for $174,000 control (or 629 of the 1290 shares) in the Cruz del Aire mine, at Sahinas Hidalgo. The latter mine was little more than a prospect only a couple of years ago, but by careful development it has opened into a notable lead and zinc producer.

JUNEAU, ALASKA.

Activity in Rainy Hollow District. — Road Building. — Borite Deposits.—Silver Bow and Yankee Basin Developments.—Halden Smelter.—Resuming Operation.

Reports from the Rainy hollow district, British Columbia, which is tributary to Haines, Alaska, indicate that this will be among the richest and most productive in the region. The erection of mine buildings, hoisting and lodging houses, and the installation of an air-compressor are planned for this winter, it being the intention to work during the entire year. A mill-site and a 30-acre town-site have been taken up not far from the mines, and it is intended to erect a smelter to treat the ore from the entire district. Copper and gold will probably be the chief products.

However, at a distance of 12 miles from Rainy Hollow, Capt. Brown's Cornes located a square mile of coal land, and on Chilcot river he has located what appears to be a large body of magnetic iron ore. A wharf and warehouse will be built at Haines to handle the freight billed through to British Columbia, thus avoiding payment of American duties.

The property of Tim Creedon is another of the good prospects in Rainy Hollow. It is on the Caster Lead, a strong silver-lead vein which is said to be traceable for four miles across country. The work done on this claim consists of 100 ft. of driving and 20 ft. of cross-cutting. There are a number of other promising properties in the district, most of them being valuable for copper, the copper being present in the form of borite. There has been no difficulty in interesting capital; all the claims that have been surveyed and checked by the owners of the remaining claims expect to be successful in procuring funds for further development.

The Porcupine district, Alaska, has been opened up as a placer country. The Porcupine Mining Co. has completed
a large flume and is now in condition to begin earnest work on its property. Results obtained so far have been encouraging and some rich gravel has been taken out. It is reported that $5000 was washed out by four men in two days from some of the best ground. The McKinley Mining Co. has also built a flume and has started work. The Alaska Road Commission has done a great deal toward making the development of these two districts possible. Although the road is not yet ready for teaming it enables the 'musher' to go through dry shod, which is a great improvement. The Canadian Government has taken up the work at the international boundary and is building the road through to Rainy Hollow. Thirty thousand dollars has been appropriated, which is estimated will cover the cost.

The shortage of water and the fall of snow will soon compel the mines in Silver Bow basin to close down for the winter. The Perseverence Co. contemplates treating the concentrate on the ground by fine grinding and amalgamation instead of shipping to smelter, as heretofore. It is likely that grinding pans will be used. Little profit is made on the concentrate after costs of smelter treatment and transportation are paid. The residue from amalgamation will go to waste. The suit in the Circuit Court of Appeals concerning certain water rights on Gold creek has been decided in favor of the Perseverence Co. A party of men with a large outfit has gone to Yankee basin to develop the Whipple mining claims. These adjoin the north end of the Eagle River property and are said to be exceedingly promising. The orebody has been found in the lower adit of the DeGroof mine on Chichagoff island and the ore is said to be of the same grade as that in the upper workings. The Hadley smelter will be blown in again soon. It will start on Minnie and Stevenstown ores, of which an abundance is on hand.

PONDERY, IDAHO.

Pondery Smelter Blown in.—Organized Opposition to American Smelting & Refining Co.—Notable Gathering of Mine Owners.

The Panhandle smelter, at Pondery, two miles from Sandpoint, Idaho, formerly owned by the Panhandle Smelting Co., and now owned by the re-organized Idaho Smelting & Refining Co., was blown in October 23 in the presence of 500 visitors from Spokane and Helena. The visitors were attracted by the fact that the existence of the smelter means life for many small mines in Montana and the Northwest. This smelter has had a checkered career since its erection six years ago. It was operated a year ago for a short time, but has never been a business success. It needed extensive enlarging and alteration to make it practicable. This has all been accomplished by the present management.

The original furnace of 125 tons capacity has been duplicated, and three roasting furnaces have been installed. One furnace and two of the roasters are yet unfinished, but the work is being rushed in order to bring the plant up to its full capacity as soon as possible. About $50,000 has been expended in the improvements, and double that amount in the purchase of ores, and the plant now has on hand enough to keep it in operation for several weeks.

Ores, however, are arriving daily from the Coeur d'Alene and Montana, and numerous small properties in Washington and around lake Pend d'Oreille are ready to contribute small amounts. The success of the smelter depends upon its ability to demonstrate that ores can be shipped from these widely separated districts in opposition to the American Smelting & Refining Co. It is being operated solely for this purpose. This attempt is due to the fact that producers of ore have for a long time felt the futility of dealing with the 'trust' on its own terms, and a movement was started over a year ago in Montana to organize the mine owners for the purpose of building their own smelter. The Montana Mine Owners' Association was formed, and quickly drew into its ranks most of the independent producers, now estimated at nearly 1000 members. The Panhandle plant being idle, and suitably situated at the junction of three railways, and in need of capital, the arrangement was made, by which the smelter was given over to the mine owners under a lease with an option to buy. The Greenough Bros., owners of the Snow storm mine, being members of the association, took large blocks of the Idaho Smelting & Refining stock, with the understanding that they would receive all the independent ore from Montana necessary to keep the plant running. Under this agreement they took over the management of the smelter. They also bought large blocks of the old Panhandle stock, and at present own a controlling interest.

The work of remodelling was begun last spring, and is now almost completed. It is planned to add new furnaces as fast as the ore supply increases and to prepare for the smelting of copper as well as of silver-lead ores. The plant is at present equipped only for the latter. Special trains were run from Helena and from Spokane and several mining men of note were among the visitors, on the occasion of blowing in the furnace. It is expected to develop the plant to a capacity of 1000 tons per diem. At present it is capable of treating 250 tons.

BUTTE, MONTANA.

Enlarging Belmont Shaft.—Cerra Shaft Dismantled.—tramway and Minnie Healy.—New North Butte Orebodies.—New Steele Process Plant Proposed.

The Anaconda Copper Mining Co. is enlarging and equipping the Belmont with the object of making it the principal working shaft of the Company for the Anaconda, Never Sweat, and St. Lawrence mines. It was surmised that this was the purpose of the Company when it took over the Belmont. In the settlement of the litigation between the Amalgamated and the Heinzé companies by which the Butte Coalition Co. succeeded the Heinzé interest. Although the Belmont is situated more than a mile south of the Anaconda, St. Lawrence, and Never Sweat mines, its deep workings of the latter are under the Belmont, and even further south. The economy of using the Belmont for mining the south vein of the Anaconda Co. is apparent.
The expense of the haul underground to and from the present shafts, and then the haul of the ore from the surface to the main line of the railroads in the southern part of the district, makes a large item. The Anaconda shaft is also fully 600 ft. above the Belmont. The latter shaft, 1000 ft. deep, is being enlarged to a full three-compartment shaft all the way down. At the 1600-ft. level it is connected with the 1600-ft. level of the Anaconda mine. The Corra surface plant is being completely dismantled. The air-compressor has been moved to the Rarus mine, and other machinery and equipment is being distributed to various mines of the Coalition and Anaconda companies.

The big Tramway shaft being sunk by the Butte Coalition and Butte & Boston jointly on property owned by both, will not be put in commission for actual mining before the first of the coming year, and in the meantime sinking will be continued, and levels opened into the Mineley Healy under the fire-zone. The Tramway is now considerably below the 1600-ft. level, where sinking was temporarily suspended while a big station was being cut at the 1600-ft. point. When the station is finished a level will be run into the Mineley Healy and sinking on the shaft will be resumed and kept up until a depth of at least 2000 ft. has been attained. In the course of the development work, 2000 tons of ore are taken out daily, in addition to about 700 tons from the Rarus mine. With the opening of the new levels a new mine is practically made out of the Mineley Healy. The fire has been walked off completely and the efforts directed toward keeping it confined to the old workings. In the Rarus, mining is being done on the 1400, 1500, 1600, and 1700-ft. levels, and a new level is being sunk to 1900 ft.

The North Butte Co. is doing some driving on the Berlin vein at a depth of 1600 ft. The vein contains a good quality of ore, but of a low grade. Cross-cuts from the Edith May are also being extended from the 1000 and 1200-ft. levels and will soon reach the Berlin vein. The result of these developments will determine the situation for the new shaft to be sunk by the North Butte on the Berlin claim. The North Butte, while mining 1400 tons of ore per day, is engaged in opening the mines on the new levels at a depth of 2000 and 2200 ft. The Edith May vein, because of its southerly dip, is close to the Speculator shaft at those levels. At 2000 ft. the south branch of the vein was cut within a distance of 100 ft. from the shaft. The vein divides some distance west of the shaft and branches eastward. On the upper levels both the south and north branch have been worked, although some good ore has been discovered at 2000 ft. From the 2200-ft. level a drift has been started westward on the south branch. A short distance from the station the orebody was opened up, containing considerable copper glance. As this is east of the point where the two branches are believed to unite, it is hoped that the vein and orebody at the point of juncture will be found unusually large and rich. Since the North Butte resumed operations, Manager Carson has kept the cost below 5c. per lb., including all costs of mining, smelting and marketing. The cost has been as low as 7.1c. per lb. for one month. The North Butte has an immense quantity of first-class ore locked out, but the average of the ore shipped is about 4.1% copper. The company makes good profit with 4.1% ore at present conditions.

The inventors and makers of the mill known as the Steele process claim that their system has not been given a fair trial by the La France Copper Co. at the Lexington mine, and they want an opportunity to establish a plant for the Butte & Superior Co. at the Blackrock mine. Negotiations are now progressing. On a lot of shipments of Lexington ore out of Dallas, Texas, where the Steele people have a large mill, the results were satisfactory, and the separation of the copper, silver, gold, lead, and zinc was quite perfect, but as soon as it was attempted to run a mill at the mine, results were different. The plant at the Lexington was identical with that at Dallas, but it did not do the same work. Some changes were made without improving results, and when the municipality of Walkerville brought injunct-

SALT LAKE, UTAH.

Fink Process at Garfield. — Bullion Beck & Champion Acquired by United States Smelting, Refining & Mining Co. — Utilizing Zinc Middling.

The demonstration at Garfield of the commercial possibilities of the Fink process for smelting is being watched with keen interest by local mine operators and metallurgists. Assurance has been given that the plant will be ready in about a month; it is being erected on the property of the Boston Consolidated Mining Co., under the personal direction of the inventor, Edward Fink, and the preliminary cost is borne by Samuel Newhouse personally. Mr. Newhouse first heard of the Fink process early in the present year, and sent his engineers to investigate; they reported that it was not without merit, and recommended the expenditure of money in conducting experiments. Accordingly, Mr. Fink was instructed to proceed with the construction of a furnace capable of treating 300 tons of ore per day. This was done, and the equipment is on the ground, ready for installation. I have obtained the following description from an authorized source. The furnace now being installed at Garfield consists of two sheet-iron cylinders, lined with refractory material, set with their ends against a central fire-box, somewhat similar to the hot-blast stove. In this instance the fire-box will be arranged to burn fuel oil, being in the nature of an oven for the heating of the blast. The charged ore is placed in the center of the cylinder, is slowly charged with coke, and the blast, together with the flame from the oil burners, is turned into the opening in the end of the cylinder over and in contact with the ore, when the gases of combustion are deflected back through the hot-blast stove to the opposite cylinder, where they are discharged from a stack. The intention is that while the charge in the cylinder to which the blast is directly delivered is being reduced, the heat of the waste gases will deflector the charge in the opposite cylinder. The operation is then reversed and the charge in the second cylinder is reduced, while a fresh charge in the first cylinder is being desulphurized. The direction of the gases, in the meantime having been reversed, the operation of smelting is made practically continuous. The simplicity of the process and the economy with which it can be operated are among the strong points claimed by Mr. Fink, together with the low cost of installation and maintenance.

The transfer of a controlling interest in the Bullion Beck & Champion mine, in the Tuttie mining district, last week, to the United States Smelting, Refining & Mining Co., has recalled some ancient history. The property was discovered about 1870 by John Beck, a devout Mormon and a four-ply polygamist, by whom it was operated with considerable success for a number of years. In the latter part of the eighties and the beginning of the nineties it was numbered among the principal silver-lead producers of Utah. Next after the adjoining Centennial Eureka mine (one of the chief assets of the United States company now), it headed the list. John Beck received dividends on his own stock to the amount of more than $1,000,000. His record of a total profit distribution of $2,738,400. Beck lost his holdings in the mine about 18 years ago, and was reduced to a state of pauperism after having arrived at a ripe old age. In late years the property has been operated mostly by lessees. It still contains some extensive orebodies, mostly low grade, which the new owner will doubtless use to advantage at the smelter at Bingham, Utah. A considerable addition to the zinc concentrate now owned by the Grasselli Chemical Co., at Park City, has been completed and is in operation, treating about 100 tons of zinc-middling from the Dal Judge mill, with which company the Grasselli management has a contract. At the Dal Judge mill are more than 20,000 tons of such middling, containing from 20 to 35 oz. zinc, 2.5 to 4% lead, and from 5 to 7 oz. silver.
Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Cobalt is remarkable for its ductility and tensile strength. It is the most tenacious of the commoner metals, being about twice as strong as iron when drawn into wire.

Cost of grading wagon roads will average from 30 to 60c. per cubic yard of earth to be handled, where no blasting is needed. The variation in cost depends chiefly on the scale of wages paid and the expense of maintaining teams. The above cost assumes the use of ordinary drag-scrapers.

Contact minerals formed when an igneous rock is intruded through limestone are chiefly garnet, wollastonite, vesuvianite, wernerite, pyroxene, and amphibole. The limestone itself would be converted into marble, which for some distance from the igneous rock would contain silicates such as those mentioned above.

Borax glass, not borax, should be used as a flux in melting gold precipitate from the cyanide process. Borax contains a large quantity of water of crystallization, which must be driven off by heat before the flux can combine with the silica and base-metal oxides present, and hence causes loss of precious metal by 'dusting.'

Carbonic acid gas is manufactured chiefly from limestone. A small quantity is made from magnesite, the residue being a valuable by-product. The total production of magnesite is small, coming almost exclusively from California, where the output in 1907 amounted to 6405 tons, estimated to be worth $57,720. Considerable magnesite is imported to the Atlantic seaboard, and efforts are being made to place a duty upon it, in order to benefit the owners of magnesite deposits in California.

Dipper dredges have not proved successful in gold-dredging operations. Their successful application in contractors' work, their adaptability to all sorts of conditions, and their relatively high capacity have led many mining companies to experiment with them, leading usually to disastrous results. A 2½ cu. yd. dipper dredge would cost from $40,000 to $50,000, and it should dig on an average 1500 cu. yd. of gravel per diem of 20 hr., allowing 16½% loss of time for proper maintenance.

Combustion-products from the detonation of dynamite under perfect conditions possess only one injurious gas, carbon dioxide, and this, instead of acting as a poison, merely reduces the amount of oxygen needed for the blood, and can produce death only when present in the air in quantities exceeding 12%, the effect being that of asphyxiation. But perfect combustion of dynamite never occurs in practice, and carelessness in making primers and in loading holes for blasting promotes the formation of carbon monoxide (CO) and nitrogen peroxide (NO₂), the former being an active poison and the latter producing serious injury to the epithelium of the lung tissues, which predisposes the sufferer to pneumonia.

Ore reserves adequate for safety in continuous mine-operation can not be stated in terms of any fixed number of years' supply. The farther ahead one can see, the better, and a wise manager will push development so as to give ample time for more extended exploration of the deposit in case the development workings for a year or two should prove unproductive. In the initial stages of a mining enterprise it is important to have sufficient ore blocked out to pay for reduction works after meeting operating expenses and fixed charges, before incurring the expense of erecting a plant. This advice seems so obviously in line with simple business judgment that the only reason for giving it is that mining companies usually do not wait until they can prove a warrant for such an outlay.

Regeneration of cyanide solutions after precipitation of the precious metals with zinc is not practiced, although A. F. Crosse several years ago proposed a method which seemed entirely feasible. The zinc-potassium cyanide in his tests was acted upon by sodium sulphide, at about 65° C., as follows:

\[ K_2Zn(CN)_4 + Na_2S \rightarrow ZnS + 2KCN + 2NaCN \]

The zinc sulphide was coagulated by the addition of a little lime, causing it to settle readily. To prevent accumulation of caustic alkali in the solution, Mr. Crosse collected the ZnS and used it to generate H₂S, which he passed through the solution after treatment with Na₂S. The two following reactions result:

\[ K_2Zn(CN)_4 + Na_2S \rightarrow ZnS + 2KCN + 2NaCN \]
\[ HCN + KOH \rightarrow KCN + H₂O \]

Mr. Crosse reported extractions of gold from Transvaal ores as high as 91% with this regenerated solution.

It is reported that the Government will specify delivery of cement-clinker instead of ground cement, for use at Panama, and will grind the clinker on the spot as needed. This would seem to be a rational proposal, from several points of view. Unground cement-clinker does not deteriorate from the effects of moisture. In fact, it may be drenched and then dried without impairing its quality. Clinker is a crystalline aggregate, and when properly burned the crystals are vitreous in lustre and a dull green in color. Imperfect burning can be immediately detected in clinker, but in ground cement this cannot be done. Adulteration is also impossible. Many cements are adulterated either with 'natural' cement or with raw ground limestone, thus weakening a really superior article as far as may be possible without impairing its ability to pass the specifications, thus increasing the manufacturer's profit. The Government's plan would insure the delivery of an honest cement, and losses in transit would be reduced to a minimum.
Discussion.

Readers of the Mining and Scientific Press are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

Tailing-Wheels or Pumps?

The Editor:

Sir—I have been greatly interested in the articles by Walter L. Reid, A. H. Jones, and others which have appeared recently in the columns of the Mining and Scientific Press, concerning the comparative merits of tailing-wheels and centrifugal pumps. It has been my fortune to have had a certain amount of experience with various types of elevating machinery during the last few years. I remember when the original tailing-wheel mentioned by Mr. Reid was installed at the Smuggler-Union 60-stamp mill, and can vouch for the fact that up to the time when I left Telluride (probably about one year after the wheel was put into commission) it had given no trouble whatever. That particular tailing-wheel was built upon an old engine flywheel taken from the Pandora mill belonging to the same company. I do not know what power was required to operate this tailing-wheel, but doubt if it exceeded 15 horse-power.

My results with centrifugal pumps have not been particularly good. The cost of maintenance, both for labor and repairs, reaches a high figure, while the power required to operate them is a serious item, especially in a mining district where power is sure to be expensive. The first cost for installation is of course considerably less than that of a tailing-wheel. In general, however, my experience would lead me to favor the tailing-wheel in preference to the centrifugal pump for constant duty against a moderate lift (up to say 30 ft.). Beyond this height, the first cost of the wheel would be a serious item, and in most cases it is probable that it would be better policy to install some cheaper form of elevator. For an intermittent load, especially where time is an important factor, I should certainly favor the centrifugal pump. For the elevation of large quantities of mill-pulp to a moderate height, however, I am strongly in favor of using the Frenier sand-pump as compared to either the tailing-wheel or the centrifugal pump. The advantages are its light weight and low first cost, extreme simplicity, and low repair-cost. At the Moatana-Tonopah mill we are using three 10 by 54 in. Frenier pumps (one spare and two in operation) to elevate our mill-pulp for re-concentration after re-grinding. They have now been in constant use for over a year, and the total cost for maintenance will not amount to more than $50. We estimate that the two pumps elevate on an average 1100 tons of pulp per day (155 tons dry sand and about 930 tons of water) to a height of 18 ft. with a power consumption not to exceed 9 to 10 hp. The pulp contains very little coarse sand, as daily screen-analyses show that about 80% of the material, although fine sand, will pass a 200-mesh screen and the wear would naturally be much greater with coarse sand.

At the Combination mill at Goldfield, however, we used the same pumps to elevate pulp before tube-milling, and the results compared favorably with those obtained with centrifugal pumps on a finer material. The principal trouble experienced when pumping coarse sand was the wear on the bearings from the gritty water, but this can be obviated to a considerable extent by extending the bearings, and by protecting them from the splash of gritty water. A certain amount of trouble was also experienced because of the pumps becoming flooded when lifting beyond their proper capacity. In my opinion the whole secret of success with the Frenier pump is to keep the height of discharge against which the pump has to lift well below the capacity claimed by the makers (Frenier & Son, Rutland, Vt.). If this is done no trouble will be experienced from flooding. At the elevation of Tonopah (6000 ft. above sea-level) the 10 by 54 in. pump is efficient for lifting to a height of 15 or 19 ft. Beyond this height I would recommend using two or more pumps in series.

Edgar A. Collins.

Tonopah, Nevada, October 14.

The Editor:

Sir—South African engineers are considering at present the advisability of discarding the tailing-wheel in favor of some other contrivance for raising the ore-pulp from the mill to the cyanide-plant. Tailing-wheels erected on the Rand before the war have been subjected to a severe test, on account of the complete suspension of the work during hostilities. While at work the rim of the wheels and the interior of all the buckets are always wet. During the stoppage of the mills the wheels were continuously exposed to the scorching sun during the dry season, and during the wet season a portion of the buckets were alternately filled with water and again dried out.

Among the many tailing-wheels then existing were two, both double wheels, that is, with two lines of buckets each, owned by the same company, built from the same design, under the same superintendence, by the same gang of men. They were in every respect alike. Each of these wheels had to raise the sand from a 200-stamp mill, with stamps of 1250 lb. weight, crushing about 5½ tons of ore per day. They were thus lifting 1150 tons of pulp, together with a large amount of water. One of these tailing-wheels was installed at the Rose Deep and the other at the Crown Deep mill. They had an inside diameter at the bottom of the buckets of 46 ft.; the number of buckets was in each case 128, each 15 in. wide by 12 in. deep. The space between the two wheel rims was 20 in., and served as a belt-drive for the wheel, with a diameter of 39 ft. The wheels had 9 in. diam. in the centre and 8 in. diam. at the journals. The bearing-blocks rested upon the top of hammer-dressed stone piers, laid up in cement. These piers stood about 30 ft. high above the foundation. The wheels made about 4 r. p. m., which gave a peripheral speed at the bottom of the buckets of 9 ft. 7½ in. per second. The wheel at the Crown Deep resumed operation evidently with-
out any trouble; the wheel at the Rose Deep broke down, and was the cause of subsequent agitation against tailing-wheels. Another typical wheel is the double wheel of the Ferreira Deep, 60 ft. diam., comprising various improvements. The space between the two lines of buckets was again used for the drive, but in this case contained 4 grooves for 13/4-in. manila rope at a diameter of 55 ft. The rope-drive contains a tension-carriage to overcome the variations in the length of the endless drive-rope, caused by the rope being alternately wet and dry on account of the extremes of temperature and moisture-conditions prevailing. By this tension-gear the tension of the drive-rope will constantly be the same. The shaft of this wheel is 14 in. diam. in the middle, and 12 in. at the journals. Another improvement in the Ferreira wheel consisted in the substitution of steel A-frames for the stone piers in support of the wheel-shaft. The four inclined posts of each A-frame are anchored to four small concrete piers, then installed, taking the pulp from the first wheel, and delivering it at the receiving-level of the new works, and both wheels have been working together with the same pulp for years.

In centrifugal pumps, the white-iron, or the manganese-steel linings, the pump-blades, and finally the shaft and bearings, will wear out rapidly, so that the pump will soon be worthless and beyond repair, and a new pump has to be substituted. At a number of the smaller Rand mines single-acting plunger-pumps, ranging from 12 to 16-in. diam. by 48 to 60-in. stroke, have been installed. These pumps require rather extensive foundations, and a very strong head-frame. These plunger pumps, and especially the valves, wear out very fast, and they require the constant attention of the engineers, and a couple of pumps will keep one machinist busy on repair work all the year round. The tailing-wheel in varying sizes and forms has been in constant use at many kinds of metallurgical works for a century or more.

and there is also a horizontal connection between both A-frames above the wheel, which gives stiffness to the structure. This wheel makes 3 r. p. m., equal to a peripheral speed of 9 ft. 5 in. per second at the bottom of the buckets. The accompanying illustration shows the Henry Nourse wheel, with a single line of buckets. In front is seen the endless-roped drive, and also the A-frames with their top-connection and the column-footings, anchored to the eight small concrete piers.

The evolution in the construction of the tailing-wheel has now progressed so far that it may be justly asserted that the wheel is substantial enough to last as long as the cyanide plant to which it is attached, subject to no important interruptions, and not involving any extensive repairs.

At one of the Rand mines, where a tailing-wheel had been installed, a further addition to the cyanide plant had been constructed; the discharge-level of the original wheel was no longer high enough for the additional plant; a second tailing-wheel was Engineers have frequently conspired against it, but it enjoys periodical revivals of favor. Tailing-wheels of moderate size, when working under shelter, may be constructed lighter and cheaper. The high efficiency of this device is indisputable, its steady working, and comparative freedom from interruption and repairs far outweigh the disadvantage of higher prime-cost and greater floor-space occupied.

G. W. Wepfer.

San Francisco, October 6.

Vesicular lava owes its porosity to the expansion of occluded gases upon relief of pressure. This indicates proximity to the surface, either in lava that has overflowed, or that has risen near to the top of a dike or volcanic pipe. It is conclusive proof that the rock did not consolidate at any considerable depth. The extreme result of sudden expansion of occluded gases in lava is the production of lapilli which form masses of tuff.
HINDS CONSOLIDATED MINES, MEXICO.

Written for the Mining and Scientific Press
By S. F. Shaw.

The property of the Hinds Cons. Mining Co. is situated in the Santa Barbara mining district, in the State of Chihuahua, Mexico. The holdings of this Company consist of 63 pertenencias, or 153½ acres, having an average length of 6600 ft. and a width of 1020 ft. Three parallel veins traverse the property, having a general northeast strike, dipping about 70° to the southeast.

The Clarines vein is the principal one worked. It extends the entire length of the property, having a width varying from 4 to 30 ft. The Clarines, Reforma, Remedios, and Santa Gertrudis workings are all on this vein. The Clarines workings have a depth of 200 ft. below the adit, which extends into the mountain along the vein a distance of 1200 ft., and reaches a point 275 ft. below the vein out-crop at the highest point. The stopes along these workings are extensive, and those below the adit have been filled with waste, as the ore has largely been worked out. A drift from the Reforma shaft, 185 ft. below the collar, connects with the fourth or bottom level of the Clarines mine. From this shaft, for a distance of approximately 350 ft., the ore is composed of sulphides in a quartz gangue. At this point a dike about 2 ft. thick cuts diagonally across the drift, and beyond this dike, where the Clarines workings commence, the ore is nearly all oxidized.

On the third level of the Reforma mine, 285 ft. deep, a drift extends N.E. a distance of 185 ft. The width varies from 15 to 30 ft. The face of the drift is about 20 ft. wide, and is in a body of lead ore, completely oxidized. This oxidized orebody occurs directly below the sulphide ore previously mentioned. The Remedios mine joins the Reforma, and the Remedios shaft is about 2200 ft. S.W. of the Reforma shaft. The Remedios shaft is 280 ft. deep, and has two levels aggregating 1600 ft. in length. A large stope about 20 ft. wide has been opened at the north end of the first level, at a distance of 190 ft. from the shaft. There is also a cross-cut to one of the parallel veins. The Santa Gertrudis workings are reached by a shaft 225 ft. deep, and by an adit 600 ft. long. From the shaft are levels aggregating 650 ft. of work.

The vein in all the workings yields mainly an oxidized lead ore carrying varying amounts of gold and silver. The principal economic minerals recognized are anglesite and cerussite, with streaks of copper minerals, such as chrysocolla, malachite, azurite, and chalcocite. Shipments of 5 to 9% copper ore have been made from the sorted material. Where sulphide ores are found the galena is accompanied by sphalerite, pyrite, and a small amount of chalcopyrite. The gold and silver is more uniformly disseminated than in the oxidized ore.

The ore from the Reforma shaft and from the Clarines adit is trammed to a grizzly made of mine rails. The oversize is fed to a 9 by 15-in. Blake crusher, set to 1½ in., and falls into a bin, joining with the fines from the grizzly. A plunger feeder delivers the ore from this bin to a 24-in. Robins picking belt, on which is sorted out the shipping ore. The mill-ore falls to a bin below the picking belt from which it is carried to the mill, a distance of 2170 ft., by a Leschen Bros. double-ropé automatic aerial tram, having a capacity of 23 tons per hour. At present the mill is not running, so the fine material is trammed to 20 compartments of hand-jigs and 4 plullillas, which are placed just below the crusher bin. These jigs make a concentrate said to average 4 gm. gold, 730 gm. silver, and 35% lead, discarding a tailing averaging 1 gm. gold, 60 gm. silver, and 1.5% lead. One man jigs about 4 tons per day, making about 0.4 ton concentrate and slime.

The main or Reforma shaft is equipped with a 10 by 12-in. double-drum geared hoisting engine, using a 1-in. wire-ropé to hoist the cage and bucket. From the collar to the second level there are two compartments, while three compartments are sunk from this level. At the Reforma, compressed air is supplied by a WB2, 16 by 18 by 11 by 16-in. Sullivan two-stage compressor, having a capacity of 600 cu. ft. of free air per minute at this elevation, and a Rand Imperial two-stage compressor having a capacity of 800 cu. ft. of free air. Machine drills are used for drifting, and various air-hammers for stoping. Light is supplied by a 7½ kw. Westinghouse direct-current dynamo, operated by a 7 by 10-in. Erie City Iron Works single-cylinder balanced-valve engine. Steam for running the hoist, air-compressors and dynamo engine is supplied by three 125-hp. Frost boilers. These boilers also supply steam for the Frost engine which drives the crusher and picking belt.

The mill flow-sheet is as follows:

1. From aerial tram-bin to (2).
2. Grizzly made of mine rails, ½ in. openings, oversize to (3), undersize to (4).
3. 9 by 15-in. Blake crusher to (4).
4. Crusher-bin to (5).
5. Plunger-feeder to (6).
6. 6 by 4-in. Sturtevant duplex crusher to (7).
7. Tronamel, 36-in. diam., with ⅛-in. round-punched openings, oversize to (8), undersize to (12).
8. 24-in. Robins picking-belt to (9).
9. Mill-bin to (10).
10. Plunger-feeder to (11).
12. Elevator to (13).
13. 2 concentric trommels, oversize from 4-mesh openings to (11), oversize from 6-mesh openings to (17), undersize to (14).
14. 2 Richards hydraulic classifiers, underflow to (18), overflow to (15).
15. Box classifier, underflow to (19), overflow to (16).
16. Cone-settler, underflow to (20), overflow to dump.
17. 4 Traylor Eng. Co. 4-comp. jigs, concentrate to smelter, tailing to dump.
18. 4 Traylor Eng. Co. 2-comp. jigs, concentrate to smelter, tailing to dump.
19. 2 ditto.
20. 2 ditto.
The fine tailing, with most of the water, goes to 4 Calow cone-settling-tanks in parallel. The overflow from these tanks is pumped to the mill supply-tank by a 9 by 8¾ by 10-in. Worthington duplex pump. The water draining through the dump is collected in a basin below, and is then pumped back to the mill supply-tank by an 8 by 6 by 10-in. Knowles duplex pump. The power plant consists of one 150-hp. Erie City Iron Works boiler, supplying steam for a 15 by 20-in. single-cylinder Atlas engine, which drives the mill machinery, and a 7 by 10-in. Erie City Iron Works single-cylinder balanced slide-valve engine. This small engine is used to operate a Westinghouse 7½-kw. direct-current dynamo, which furnishes light for the mill and for the Remedios mine. The power required to drive the mill machinery is 110 hp., with a consumption of 8¾ cords of wood per 24 hr. The saving made in the mill is about 48% of the assay-value. The ore treated is largely oxidized, which accounts for the low extra-

**Pumice is a term** applied to a form of volcanic rock which may be either massive or in a finely comminuted state. The massive variety is largely imported from the Lipari islands. This rock owes its peculiar porous, vesicular, or pumiceous condition to the rapid expansion of occluded moisture or gases on the sudden release of pressure at the time of its ejection from the volcano. This expansion may be carried to such an extent that the rock is completely shattered, and the resultant finely powdered material may be carried to unknown distances by wind and air-currents and then deposited in beds. This explanation is usually assigned to the Nebraska deposits. Practically the entire State of Nebraska is said to be underlaid by natural pumice, deposits of which extend as far east as Omaha. The **extent and thickness** of the beds are evidence of extraordinary former volcanic activity. North of Nebraska, in the heart of the Bad Lands of South Dakota, beds of pumice 10 to 15 ft. thick have been noted. In Scotts Bluff and Banner counties, in the western part of Nebraska, there are beds 100 ft. thick, which, though not consisting wholly of volcanic ash, have been rendered white by it. The material in individual beds differs greatly in purity, texture, and physical condition. Some is pure white; some is adulterated with silt, sand, clay, and particles of limestone. In texture also it exhibits great variety, the materials being found in almost every stage of consolidation, from incoherent dust to fairly compact rock. Nearly all the material is used for abrasive purposes, either in the form of polishing powders or soaps. Deposits of a substance resembling volcanic ash occur in three isolated beds lying within a radius of four miles from Durango, La Plata county, Colo. The material, which is similar at the three localities, is a dustlike powder of white opaque flakes, glistening in the sunlight, and is gritty and entirely unconsolidated. Some of the possible uses for this material are in semiconfused filling-brick, in fire-proofing, and in mineral-wool for packing as a non-conductor of heat and sound. In its natural condition it might also be used in refrigerating plants, in the manufacture of puzzolan cements, and in some of the cheaper varieties of glassware. The production of pumice in the United States in 1907 amounted to 512 short tons. The price realized was $4.17 per ton.

The **production of copper** in the United States, Mexico, and Canada during September is estimated to have been 102,509,125 lb., an increase of 34,120,352 lb., as compared to the corresponding month a year ago, and 4,547,125 lb. more than September, 1906. Owing to the restriction of production at Butte early this year, it is probable that Arizona will be the leading copper region for 1908.

**Hinds Consolidated Mill, Santa Barbara, Mexico.**
BETTER PROTECTION OF MINE INVESTORS.

Discussion by the New York Section of the Mining and Metallurgical Society of America.

H. S. Murro.-The subject may be considered under three heads, corresponding to the three principal phases in the life of a mine, namely, prospecting, development, and working. Each of these three phases presents its peculiar problems. Mining differs from other industries, in that the risk of failure is much greater, and that, as far as any given property is concerned, the business is necessarily a temporary one. On the other hand, the profits may be great.

The risk of financial loss and chances of failure in mining are greatest at the beginning. The vast majority of mineral deposits are not workable. The prospector's chance of success is small, and most of them live and die poor men. The investment of capital in prospecting is about as profitable as stock-gambling, and the investor is fortunate if his gains balance his losses. To maintain the supply of mineral products necessary to modern civilization, new deposits must be discovered and developed as the old are exhausted. In all civilized states this necessity is recognized, and every encouragement is given to those who search for and develop the mineral wealth of the country. In the discovery and development of new mineral deposits the expenditure of time and money is out of all proportion to the results obtained. Out of thousands who have rushed to new-mining regions, the great majority have returned poorer than they went, and many have lost life as well as time and money. But little can be done to check this economic waste of money and human energy. The spirit of adventure and the desire for great wealth quickly gained cannot be controlled. The best that can be done is to aid and guide the prospector and increase his chances of success, and lessen the inevitable hardships as far as it is possible to do so. This is a proper field for Government activity. Effective protection of life and property, carefully framed and wisely administered mining laws, and the scientific study of mineral deposits and their geological relations by trained mining geologists, may do much to lessen the economic waste and great losses incidental to the original discovery and development of the mineral resources of the nation.

There is also great economic waste in the development of mines. Out of several hundred promising discoveries, but one or two become profitable mines. Each of these unsuccessful enterprises will have hundreds or thousands of dollars expended upon it before work is abandoned, and the annual waste of wealth in such unproductive mining ventures is very great. In the early history of any mining enterprise a certain risk must be taken. It is impossible to determine the worth of most mineral deposits without the expenditure of much money in development work. In the majority of cases, however, through ignorance or over-confidence, and sometimes through dishonest management, much larger amounts are expended than are at all necessary to prove the value or worthlessness of the property. Unfortunately, this loss of money by unwise and unnecessary expenditure falls on those who are least able to afford such loss. Large capitalists can command the services of skilled mining engineers, and rarely undertake development of mining properties unless the chances of success are good and the risk of failure is small. If it were necessary to depend entirely on men of large resources for the initial development of new deposits, but few new mines would be opened, and the industry of mining would be more likely to decrease than to increase in importance. The original work of development, and the work of proving the value of new discoveries then falls on the prospector and his associates, the small capitalists whom he can succeed in interesting in his discovery. This has proved a rich field for the unscrupulous promoter, who forms a connecting link between the prospector and the small investor, and preys upon both. Mining as a business is of necessity attended with risks, especially at the beginning, when the extent and value of the deposit are unknown. The risk is offset by the chance of large gains if the property proves valuable. Mining must be carried on by those who are willing to take these risks, in the hope of winning one of the prizes. The many failures tend to make the investing public more cautious, but nevertheless, the unwise and unnecessary expenditure of money in the development of mineral resources is a serious waste, which well deserves the consideration of economists and statesmen.

The multiplication of mining schools in all parts of the world undoubtedly does much to check this economic waste by furnishing a large body of trained students of mining, who develop in time into mining experts competent to advise investors, and lessen unwise and unwarranted expenditure. The work of the United States Geological Survey, and the bulletins and monographs on mining regions, has done much to lessen unwise expenditure and increase the chances of success in the development of mineral properties in this country. Whether it is wise or practicable for the Government to concern itself with individual mines or mineral properties is doubtful, but it is a proper and perhaps may prove a profitable subject for discussion. While the property is under development by the prospector and his associates, governmental interference is impracticable. The authorities can offer aid and advice only. When, however, a public corporation is formed, seeking capital by public subscription, such company must be organized under State laws, and may be controlled. It has been suggested that an application for a charter should be accompanied by satisfactory evidence of real value of the deposit to be worked. If some such provision can be incorporated in the laws of the principal States, with suitable machinery for its enforcement, and effective provisions against abuse, great good might result.

The tendency on the part of the investing public to exaggerate the value of productive mines also tends to the ultimate injury of the mining industry. The uncertainties attending the development of mining properties, and the possibility at any time of
new discoveries adding greatly to the value of the mine, tend to encourage speculation in mining stocks. Mine investors are naturally sanguine, and it will always be impossible to prevent or even control this speculative tendency, which is by no means confined to shares in mining enterprises. Old and well developed mines, however, are rarely subject to such fluctuations in their actual value as is the case with smaller and undeveloped properties. There is no reason why such properties should not be removed from the speculative class of investment and recognized as a form of legitimate business. To this end the mining investor should be better informed as to the real character of the business of mining. This duty properly falls on those in charge of such mines, and to those who are called upon from time to time to advise investors as to the value of mining properties. It should be strongly impressed on the investing public that mining differs radically from other productive industries, in that it is of necessity a temporary business. Every mineral deposit is sooner or later exhausted. The business of mining must be so managed that the money paid for the mineral property, expended in its development, and spent for the necessary plant shall be repaid from the earnings during the life of the mine. Certain mines may have a very long life and the amortization charge per year may be small. Other mines are likely to be short-lived. In the majority of cases a mine should earn not less than 20% on the investment to be profitable. The actual value of a mine is not often more than five times its annual earnings. The shares of well known and profitable mines are frequently sold in open market on the basis of 10 or 12 times the annual dividends. The purchaser at such prices usually makes an unwise investment, and sooner or later must face serious loss. This is particularly the case when the earnings of the mine are temporarily above the average because the mine is in bonanza, or because the product commands for the time being a high price in the market.

This tendency toward the over-valuation of the shares of successful mines and the great waste of money in unsuccessful enterprises, and the large losses to investors resulting therefrom, work greatly to the disadvantage of the mining industry, and tend to check its development, by increasing the difficulty of raising the necessary capital. It is therefore to the interest of any mining State, by wisely framed mining laws, by well organized geological surveys and well endowed mining schools, and by well considered legislation looking toward the better protection of mine investors to lessen this economic waste, and to endeavor to place the business of mining on a saner and more conservative basis. The mineral resources of any State constitute an important source of wealth which should be wisely administered for the advantage of the people.

J. R. Finlay.—During the past year a rather extended study of the reports of American and foreign mining companies, undertaken for the purpose of finding out as much as possible about the value of their various properties, has impressed me not only with the lack of uniformity in making statements, but with the apparent lack of a feeling of responsibility by the directors of a large proportion of the American companies in the matter of giving their shareholders any adequate information regarding the conduct of the business. It seems to me that the Mining and Metallurgical Society of America might use its influence to show to managers of mining companies the necessity and desirability of giving their stockholders such reports as will enable these to form a legitimate idea of the value of the business in which they participate. It is well forth considering whether we cannot, after a full discussion, recommend to the public a form of official statement which will include the minimum of essential facts that will be acceptable. It may be possible even to recommend legislation by the States to compel companies to furnish proper information.

Some of the largest concerns are the worst offenders. For example, the United States Smelting, Mining & Refining Co. issues a report containing the following information: List of officers; statement of earnings for the year; output of metals; balance sheet; statement of capital stock and securities issued; a general perfunctory description, without any details, of various properties owned. In selecting this statement I am not picking out by any means the worst example. This report does give information. The criticism to be made, however, is that it goes through the motions of giving information without disclosing anything really vital. It does not show the value or resources of a single one of the properties, gives no idea of the cost of operating any of them, of the ore resources they contain, nor of their probable life. With these essential factors left out, the stockholder is compelled to make an absolute guess as to the value of his property. The statement of earnings means nothing unless one knows how the earnings are obtained. It is conceivable that earnings might come from some sources of quite temporary character. It is also conceivable, and very often happens, that the so-called earnings are only nominal, because a large portion of them may have to be put back into the property for various reasons.

It may be said as an excuse for this type of report that a large concern like the United States Smelting, Mining & Refining Co. owns too many properties to be readily described, and that a report so describing them all might be too cumbersome and expensive. If such a feeling is in the minds of the managers of these corporations, it seems to me our influence ought to be directed to relieve them of it.

Most English mining companies give information that, I believe, is prescribed by laws which are nearly uniform throughout the British Empire. Without going into unnecessary detail, I may cite as an example the report of the Great Gingolly Consolidated, of West Australia, managed by Bewick, Mooreing & Co., of London. This report contains the following features: Notice of advertisement of the general meeting of the stockholders to receive reports; list of directors and officers; report of the directors, giving a general account of the condition of the property, including the amount of develop-
ment work, the tonnage mined, the values recovered, the costs of operating and profits for the period reported on; balance sheet of the company's account; profit and loss statement, including a revenue and working cost statement: appropriation statement, showing the disposition made of all earnings; report of the managers, including details of development, ore reserves exposed on three sides, probable ore, not so thoroughly exposed, working expenditures, construction accounts, general remarks on the condition of the property, and a map of the property. When these points are fully covered in a statement over the signature of the responsible officers, and are duly published, the stockholder can be pretty sure of knowing about what his interest is worth to him.

Some companies, both in this country and in England, go still further. The Tennessee Copper Co., for instance, covers a point included in the Great Fingall report in a rather better way than the ordinary, by including in the balance sheet, not the ordinary perfunctory statement of assets and liabilities, but an actual record of the capital expenditures on the property from the beginning, in considerable detail. This is a most important point, and, I believe, should be included in a really satisfactory report. Some companies, notably the Alaska Treadwell group and the mines managed by John Taylor & Sons, of London, give in addition an abstract of the results obtained from the mines from the beginning, including the tonnage and values realized each year, the working profits and the dividends paid each year, with the totals for the whole period. This information, put into compact statements, throws into relief the present performance of the property, compared with its past performance, which is perhaps the most vital factor in sizing up its condition.

Elaborating on this idea, F. W. Bradley has recently issued a circular to the stockholders of the Bunker Hill & Sullivan Mining & Concentrating Co., that goes a step further.* It gives the estimate of ore counted on, with the methods used in making the estimate, and then proceeds to give the actual record of the property from the beginning, including the average assay-value and average recovered value of the ore at various periods, the tonnage produced, the complete cost of operating, the expenditures for plant, the prices obtained for metals, and the market conditions that have ruled at the various periods, and the dividends paid. From this is obtained a forecast of future expectations made up by Mr. Bradley from a consideration of these data.

There may be great difficulties in the way of furnishing certain information, but it seems to me that, as a general thing, a stockholder in a company is justly entitled to whatever knowledge of the property may be necessary to enable him to know its value. This matter has become more or less a political question in the last few years, and a definite call for settlement of it is likely to be made.

Edward L. Dufoire.—The society as a body cannot practically do nothing to protect those who are venturing into the field of opening prospects, because the very nature of the work undertaken at this stage of mining operations involves more than the ordinary 'mining risk.' The degree of reasonable expectations for each district must be made a special study under conditions that vary widely, and no set rules as to what information a stockholder should have in a company undertaking such operations can be laid down. The only protection that he can look for is in the advice of a reputable engineer who has studied the particular district.

In considering what may be set by the society as a standard for the reports of companies actually operating, whether quarterly, semi-annually, or annually to be rendered to stockholders, it must be remembered that producing companies pass through two stages, namely, that in which new capital is continually being applied for installation and increase of plant, during which the company approaches its maximum of output, and that in which, the maximum having been attained, the shares generally reach an inflated value, when unscrupulous 'insiders,' taking advantage of information withheld from the average stockholder, find an opportunity to unload their holdings. It is in the latter stage especially that the exaction of complete information as to the condition of the mines and plant may be of value in the protection of stockholders and investors.

The annual statements of operating companies should be required to show, among other matters: (a) Amount of expenditure on capital account, and whether for plant, properties, or in case some of the development work is charged to such account, the proposed rate that this is to be charged off subsequently to operating account. (b) Operating expenditures, showing what part of same is for direct operations, and what for repairs and renewals; also what amount is used for mining developments. (c) Administration expenditures, showing salaries paid to officials and the cost of maintaining the home office, and legal expenditures. (d) Gross and net value of ore, bullion, or other product realized during the year. (e) Tonnage and grade of ore in sight and on the dumps and the net estimated returns from same. (f) Division of profits into amounts applied to dividends and the amount carried to reserve or to surplus.

In requiring information covering the above points to be set forth in the annual statement of operating companies, we must remember that a great many mining companies in reality are only holding companies. In the case of a holding company, the annual report should state the amount of its holdings in each of the subsidiary companies, and information as to each of the subsidiaries should be available along the lines indicated for operating companies.

I do not believe that immediate benefit could be obtained by the establishment of a Federal Bureau, since the occasions for delay in spreading information through means of a Federal Bureau would be too many, and there would be too many opportunities for evasions on the part of companies in furnishing the information. What the Society can best hope

---

*Variations in Mining Costs,' Mining and Scientific Press, July 4, 1908.
to do is to force its standard for reports upon those companies which will hope to retain the confidence of their stockholders by having the seal of approval of a well-known recognized body of reputable engineers.

Another point which the Society might hope eventually to have established is the undoubted right of an engineer, for his own protection as well as for the protection of investors, to insist upon the publication of reports in full, and not in part.

J. F. Kemp emphasized the importance of correcting the false ideas of the mining business which prevail in the minds of the general investing public. No adequate conception of the risks and difficulties exists, so that people of the best intentions are exceptionally easy marks. One cannot but deplore also the enormous capitalized characteristic of so many enterprises whose operations are carried on rather for profits in the stock market than from the ore. Of course, the old legal maxim of caveat emptor applies, but on account of prevailing ignorance and misconceptions, unfortunate conditions of this kind are all too characteristic of the mining business. The Society may well do what it can to cast its influence on the side of lessening these objectionable features and spreading accurate general ideas. As regards the fulness of publication regarding reserves and resources, wisely advocated by Mr. Finlay, no doubt many operators are somewhat justifiably apprehensive of the tax collector. Like other uninitiated people, assessors are influenced by the booming and exaggerated talk of the promoter, and are disposed to evaluate properties above what is just. A case in point is the Provincial Government of Ontario, whose disposition was manifested in the Parliament at Toronto, a year and a half ago, to tax the Cobalt and other Ontario properties on the basis of ideas of value, widely disseminated but scarcely warranted. At the same time, and with a proper appreciation of the need of caution in these and other regards, it might be very desirable to provide in the terms of incorporation, and as conditional thereto, for reports of a sufficiently detailed character to convey to stockholders, and others, facts of reliable significance.

W. Y. Westervelt.—While in entire sympathy with the movement to have the Society determine what it can best do to protect the investor in mining shares, I must admit that thus far I have been most impressed with the difficulties in the way. Take, for example, the attempt to give the stockholders an idea as to the value of their holdings by stating the profit-making value of the ore deposits; how is the question of the immense amount of modifying influences exerted by change of character in the ore, by development of processes, and by greater economies in size of the plant, which make such immense fluctuations in the value of the ore resources, to be handled?

The usual elaborate report, discussing the pros and cons of such influences, which is rendered by the engineer to the board of directors, would, I cannot but feel, be of very doubtful value in the hands of the average stockholder, who has neither time nor inclination, even though he possess sufficient knowledge of the business, to digest the purport of such reports. My experience has been that what the average successful investor (outside of the actual leaders of enterprise) wants to know is what his stock is worth today, or going to be worth tomorrow, and such question is so inextricably interwoven with the financial support, market conditions, and skillful business management of the property, as well as its intrinsic worth, that I am sure all will agree that the engineer cannot proceed with too much caution in advising as to the immediate dollars and cents value of a particular security. By this I do not mean to in any way attempt to discourage the effort on the part of this Society toward a wiser and more uniform publicity in the handling of public corporations engaged in mining business, but I am particularly impressed at the moment with a sense of the caution with which the subject must be handled, lest more actual harm than good be done.

Graphite appears in the market in three distinct forms—crystalline (or flake), amorphous, and artificial. All are used to some extent for the same purposes, but there are some uses to which each kind is specially adapted. The coarser and purer forms of crystalline graphite, known to the trade as lamp graphite and chip graphite, are used for the manufacture of crucibles, pencils, lubricants, and electrotypes. Cheaper grades of crystalline graphite, known as dust and sweepings, are used in the manufacture of stove polish, foundry facings, and paints. Amorphous graphite is used for purposes where purity is not a prime requisite. Thus a graphite rock mined in Georgia is ground and put into phosphates used for fertilizer, as a black color is demanded by consumers, on the supposition that it means better quality. In Michigan graphite rock is ground for use in paint. The distinction between crystalline and amorphous (non-crystalline) graphite is, however, not easily defined. Some of the graphite that is termed amorphous differs from the crystalline only in the microscopic size of the flakes; on the other hand, amorphous graphite may be more closely related to anthracite coal than to crystalline graphite. An example is found in the Rhode Island deposit, formerly known as anthracite coal, but which now furnishes commercial graphite. The purest graphite is carbon with 0.05 to 0.20% of hydrogen, but the commercial grades of crystalline graphite contain clayey impurities, even the best, such as some of that from Ceylon, comprising as high as 15% of ash. Artificial graphite was first put on the market in 1907, and its production has increased steadily each year since that time. Although manufactured by a single company, the output for 1907 was of greater value than that of the combined production of flake and amorphous graphite. The material was first manufactured for use in electrolytic processes, but it is now sold for many of the purposes for which crystalline graphite is used.

The ruby sand of the beach bordering the Bering Sea at Nome contains garnets with the gold; it is to the color of these garnets that the concentration owes its hue and its name.
ZINC SMELTING FOR PIGMENT.

Written for the MINING AND SCIENTIFIC PRESS
By EVANS W. BUSKERTY.

Zine pigment in some form is the base of nearly all high-grade modern mixed paints. Formerly zine oxide was considered an adulterant in white lead, and was, of course, under the ban. It was found, however, that zine pigment added materially to the good quality of the paint. Consequently, in spite of the opposition it first received, zine pigment has steadily encroached upon the field formerly occupied by white lead alone, until it has gained recognition as a standard paint.

In 1848 the New Jersey Zine Co. built a plant at Newark, New Jersey, and attempted to smelt zine by the Belgian method, but was unsuccessful on account of the presence of iron in the ores, which corroded the retorts. Richard and Samuel Jones then devised a process for the manufacture of zine oxide, which was modified in 1851 by Samuel Wetherill. This process, with very little modification, is used by the New Jersey Zine Co. at the present time. Zine oxide and zine-lead pigment may be made by the same process, and the same plant is often used at different times for the manufacture of either, as desired, the only precaution necessary being a thorough cleaning out before each change of product.

The ores used for the manufacture of zine oxide are the sulphide and the carbonate free from lead. The presence of iron is not detrimental. Zine-lead pigment is made from ores containing a mixture of zine-blende and galena, zine carbonate and galena, or a mixture of the three. These ores come largely from Colorado, New Mexico, and the Republic of Mexico. Before the development of the zine-lead pigment industry these ores were waste products, being too low in lead, gold, and silver, and too high in zine, for the lead smelters; and they were too low in zine and too high in lead for the zine smelters. Within the past 10 years two plants have been built, one at Canyon City, Colorado, and one at Coffeyville, Kansas, for the manufacture of zine-lead pigment from such ores. This has created a demand for them, and thousands of tons have been made into zine-lead pigment of a highly satisfactory quality. Any of the mixed zine-lead ores of the West are adapted to this process, but ores free from antimony, bismuth, arsenic, and cadmium are preferred, as the presence of these substances is detrimental to the color of the pigment. Ores for use in this process should contain at least 30% lead and zine combined. Ores of a lower content than this are too costly for smelting, in proportion to the amount of pigment produced. The amount of labor required to smelt low-grade ore is the same as for high-grade, while the amount of coal consumed is greater.

The proportions of the zine and lead should be as near 2 to 1 as possible, this proportion making a pigment containing about two-thirds zine oxide and one-third basic lead sulphate. An ore containing 22% zine and 11 lead, or a total of 33%, would be a desirable one. If these proportions do not exist in the ores, they may be bedded in such a manner as to produce the proper mixture.

At the Coffeyville smelter the ores are bought on a 30% basis. For every per cent that the ore falls below that amount a 'docking' is made, and for every per cent above a premium is paid. Gold, silver, and copper are not paid for, but the slags from ores containing these metals are saved, and shipped by the owners to the lead or copper smelters. The copper in the slags has been about as high as in the ores, there being no concentration. The silver, however, suffered a loss of from 25 to 50%, the amount depending entirely upon the heat at which the charge was smelted. The ores contained on an average less than 3 oz. silver per ton, and rarely more than 10 oz. Ores containing silver may be smelted by this process at a much smaller loss by maintaining a lower temperature.

The ores are paid for on the combined assay, and are umpired accordingly. When the assay on one of the constituents varies as much as 1% the ore is umpired. In umpiring both lead and zine are assayed, although the difference might have occurred in the assay of only one of these metals. The settlement is made on the combined assays of the two metals as reported by the umpire. The ore as it arrives at the smelter is mostly coarse, having been hand-sorted at the mines. Only a small amount of concentrate is bought. Most of the ore comes from the Kelly and Graphite mines, Magdalena, New Mexico. It is unloaded at the crusher, which was built by the Allis-Chalmers Co. The crushing plant is equipped with Blake crushers, rolls, elevators, screens, and automatic samplers. The ore is crushed to 1/4-in. size, and elevated to the bins. From the bins the ore goes to two McDougal furnaces, where it is roasted down to 3% sulphur. The ore originally contains from 15 to 25% sulphur. The two McDougal furnaces have a capacity of about 50 tons per 24 hours. The roasted ore is dumped into brick cooling-bins and is allowed to cool for several days before it is taken to the oxide furnaces.

The oxide furnaces differ materially from those used in the Wetherill process. They are built individually, being open on three sides, the back being built against a large flue. At Coffeyville the furnaces are in blocks of nine grates to the block. Two blocks are built with their ends opening into a combustion chamber at right angles to them, as shown in the plan. The grates are 6 by 12 ft., and are flat. The ash-pit under the grates is partially filled with water, to prevent the grates buckling. The grates are made of cast-iron, 1 1/2 by 8 in. by 6 ft., perforated with holes 1/2-in. diam. and 1 1/2 in. apart. The blast enters through these holes. The blast is furnished by two 3-ft. fans made by the American Blower Co. They are driven by a 30-hp. motor. The blast enters through the bridge-walls between the sets of grates, and passes into the charge through the holes in the grates. The products of combustion are carried off by a No. 160 American Blower Co.'s fan situated at the bag house. This fan has a suction 4 ft. diam. and a discharge 3 ft. square. The bearings are water-cooled.
In operating these furnaces a layer of coal is first charged evenly upon the grates. When this is burning freely the charge of roasted ore and coal, intimately mixed, is thrown in and spread evenly. The door is now closed, and the ore begins to burn. If, after a few minutes, the door be opened, the whole interior of the furnace will seem to be ablaze with the oxides of the burning metals. The smoke, or fume, impelled by the powerful blast, rises and passes into the combustion-chamber, where the carbon and other impurities are burned off. Passing through the combustion-chamber, it enters the cooling-pipe, which is of sheet-steel, 700 ft. long, its purpose being to cool the fume in order to prevent the burning of the bags. The cooling-pipe connects with another settling-chamber near the bag-room, from which the fume enters the large suction-fan which forces it into the bags.

Connecting with this fan at right angles is a sheet-steel conduit called the 'breech.' From this 18 conduits branch at right angles. These carry the bags for the sifting of the fume. There are 50 bags above, each 30 ft. long, and 17 bags below that are 8 ft. long. The long bags are suspended from the girders at the top of the building.

The fume flows along the conduits and enters the bags, the gases being forced through while the pigment remains on the inner surface. The bags are shaken every four hours, when the pigment falls into the hoppers, and thence into the short bags. Every 24 hours the short bags are removed, and after cooling they are loaded into wheelbarrows and emptied into a conveyor at the end of the building, by which the pigment is carried to the packing room. There it is packed into barrels of 400 lb. each, using packing machines made by Barnard & Less, of Moline, Illinois.

W. E. H., Pioche, Nev.—No. 1, shale; No. 2, metamorphic shale, with films of lime and dendritic manganese oxide.

A. Q. M. Co., Angels Camp, Cal.—No. 1, quartz mica-schist with small amount of amphibolite schist; impregnated with pyrite now altered to limonite.

C. G. S., Silverbell, Ariz.—No. 1, metamorphic shale, perhaps a schist in the field; No. 2, silicified andesite; No. 5, rhyolite, perhaps grading into dacite in the field; No. 6, granite porphyry impregnated with pyrite and chalcopyrite.

F. S. S., Bakersfield, Cal.—No. 1, biotite-schist with a few sulphide crystals; No. 2, basic diorite, slightly schistose, traces of sulphides; No. 3, fine-grained schist, similar to No. 1; No. 4, yellow powder composed chiefly of calcium carbonate, making a marly soil.

H. A. C., Ingot, Cal.—No. 1, Lode matter, consisting of quartz and caleite, with iron oxide and some remnant of unoxidized pyrite; No. 2, iron oxide with zeolites, probably resulted from alteration of a very basic volcanic rock; No. 3, zinc-blende with quartz and caleite and a little galena.

C. E. S., Sweetwater, Nev.—No. 1, metamorphic shale; sandy; No. 2, arsenopyrite; No. 3, metamorphic shale; No. 4, quartzite; No. 5, galena with a little quartz; No. 6, garnet magnetite mass with traces of copper as chrysocholla; a contact rock; No. 7, rock, probably metamorphic shale, almost entirely decomposed, and filled with limonite after pyrite; No. 8, quartzite.

L. A. F., Virginia City, Montana.—No. 1, pebbly clayey soil, an alluvial deposit; No. 2, thoroughly decomposed rock, probably an andesite, now practically a clay soil; rock may have been acted upon by hot mineral water; No. 3, decomposed rock, similar to No. 2, but in a further stage of alteration; No. 4, garnet-magnetite sand, with some quartz and feldspar.
THE ROBINSON MINE.

Written for the Mining and Scientific Press
BY J. B. PITCHFORD.

The most productive gold mine in the world at the present time is the Robinson at Johannesburg, South Africa. It has paid $30,000,000 in dividends from a total production of 2,711,345 oz. of gold. It covers part of the main-reef series of veins, constituting a lode that has been traced for about 70 miles, with a dip that is steep at the outcrop, but flat in depth. Along the line of this lode there are about 80 mines being worked and supplying ore for $500 stamps, crushing from 5 to 9 tons per stamp. The town of Johannesburg is near the centre of this district. The ore is a conglomerate consisting of pebbles bedded in a vitreous quartzite; the pebbles are egg-shaped, and vary in diameter up to 8 in. The Dutch term for the lode matter is 'banket,' and for the pebbles it is 'cape.'

The Robinson mine is situated on the farm Langlaagte, upon which the first discovery of 'banket' was made by an employee of the Struben brothers in 1886. It adjoins Turfontein, the mynpacht (or mining right) of which is included in the Robinson property. Some of the ore was sent to Kimberley and was pumped in the presence of several influential men of the diamond mines; among these was J. B. Robinson. Upon seeing the results of the panning, Robinson went to see the new discovery, and in July 1886 he purchased the Langlaagte estate for £7600 (about $35,000) and in September he purchased a half interest in the De Villiers mynpacht.

The Robinson mine is one of the largest and most important in South Africa. It is situated in the Transvaal colony, about 25 miles west of Johannesburg, and covers an area of 1,000 acres. The mine is worked by the Robinson Consolidated Gold Mines Limited, a company of British capital, and is managed by a British mining engineer, Mr. J. B. Robinson.

The mine is worked by the open-cut method, and is equipped with the latest mining machinery. The ore is crushed and treated by the cyanidation process, and the gold is recovered by the amalgamation process. The mine is worked by 700 men, and produces an average of 2,000 oz. of gold per day. The mine is expected to be worked for at least 20 years.

but to assure a successful future. From 1896 to 1903
the mine was under the management of H. B. Price,
who continued the good work except during the in-
terruption of the war period, which commenced in
October 1899. When the war began the mines were
operated by the Boers for the benefit of their own
government. Those mines having a preponderance
of non-British shareholders were worked by the
company's staff; others, like the Robinson, were
managed by the Government. The State mining en-
gineer took control of the Robinson, which had filled
with water to the twelfth level, the mill was run to
produce gold for the Boer Government, the foundry
and machine-shops were used for other mines, and
a government refinery was conducted under the
management of Mr. William Bettel. The best mines
were thus worked to produce the sinews of war for
the Boers and the last gold shipment to England
was captured at Elandsfontein on the day war was
declared, the mail and express car being uncoupled
from the Cape Town train and sent to Pretoria with
its gold bars. After Lord Roberts entered Johnes-
burg all work was suspended on the mines until May
4, 1901, when the Meyer & Charlton mill started 50
stamps. On May 6 the Robinson and Treasury mines
started their mills. It had been the intention of
some of the Boer officials to destroy the mines be-
fore Lord Roberts entered Johannesburg; holes had
been drilled in 25 shafts and 40 holes had been
drilled in the main shaft of the Robinson mine from
a depth of 5 ft. to 500 ft. down for the purpose of
blowing up the shaft. But good sense prevailed
and this scheme was not carried out, although at a
later period of the war the works of the New Klein-
fontein were destroyed by the Boers.

In 1903 William M. Mein, a son of Thomas Mein,
was appointed to the management of the Robinson
mine. He graduated from the University of Cali-
ifornia, having had a previous metallurgical train-
ing. By reference to the tabulated statement of
operations it will be noted that the gold output and
the decrease in the working expenses has pro-
ceeded regularly under Mr. Mein's management, and
he has since been promoted to the head of the cen-
tral administration of a number of important mines;
his former position in the Robinson is now being
filled by R. C. Warriner, who has had a large ex-
perience on the Rand.

The Robinson mine is within a mile of the centre
of the town of Johannesburg. There are two shafts,
one inclined about 40° and one vertical. The de-
velopment of the orebodies has been complete to
the boundaries of the adjoining properties, in depth
as well as strike. The law of the Transvaal gives
rights limited by the surface boundaries continued
vertically downward; no apex right is recognized.
The owner is not allowed to work nearer than with-
in 30 ft. of his boundaries except by permission of
the State mining engineer; and this permission is
not given except by agreement with the owner of
the adjoining ground. The surface plant includes
two shaft head-frames with bins and sorting ap-
pliances, mechanical haulage to convey ore to the
210 stamps, air-compressors of about 200 drills en-
pacity, electric light and power plant, four tube-
mills, a cyanide plant having steel vats 30 ft. diam.,
a compound to accommodate 2500 Kaffirs giving a
minimum of 250 en. ft. of air space for each man
and fitted with angle-iron bunks and removable
boards, a hospital, houses for married employees
fitted with bath and other modern conveniences.
There is a recreation hall, billiard-room, reading-
room, and boarding-house for the employees, and
there is a resident physician on the property.

Notwithstanding all the interruptions of the war
and subsequent labor troubles, the mines have been
managed so that unnecessary friction has been
avoided and the shareholders have reaped the bene-
fit due to the harmonious co-operation of the work-
ers and a well organized staff under intelligent di-
rection, without which the desired results cannot be
accomplished. As there have been a number of
American mining engineers engaged on the Rand,
it may be interesting to mention some of the events
in which they took part.

There was considerable dissatisfaction among the
Uitlanders on account of their not having sufficient
representation in the Government of the Transvaal
and, considering that the mining industry paid over
90% of the taxes, they thought that they were en-
titled to representation in the Volksraad. The time
formerly required for naturalization had been ex-
tended by the Boers, and some of the English
wanted to vote without severing their allegiance
from England on the plea that Great Britain was
the suzerain power in the Transvaal. The gold tax
on the net output at this time was 5%. A dynamite
monopoly working under a Government concession
was charging 50% more for explosives than is charged
at the present time, and $5,000,000 per annum was being paid for this item alone. The Nether-
lands railroad was another semi-government con-
cession that charged all the traffic would bear, and
Oregon pine costing $14 to $16 per thousand feet at
Puget Sound would cost $75 to $80 per thousand de-
divered at Johannesburg. These exactions tended
to foment trouble; after considerable agitation a re-
form committee was organized, and Capt. Thomas
Mein was elected chairman. The committee invited
representative men to interview President Kruger
with a view to making some adjustment of the dif-
ferences existing between the Boers and the Uit-
landers. The men selected were Charles Leonard,
Lionel Phillips, Francis Rhodes, and John Hays Ham-
mond, the last being then consulting engineer to the
Consolidated Gold Fields of South Africa. While
the question of organization was being discussed by
the reform leaders, Dr. Leander S. Jameson made a
reckless dash for Johannesburg without the sanction
of the reform committee. The result was that
Jameson and his 500 men were defeated and cap-
tured by the Boers after a running fight from near
Krugersdorp through Randfontein to Doornkop, and
on January 1, 1896, they were brought into Johan-
nesburg as prisoners of war. The complicated con-
troversy events that led up to the raid and Cecil
Rhodes' alleged connection with Dr. Jameson are
regarded from different standpoints by English and
Dutch. Shortly after the raid there was a terrific explosion of several cars of dynamite on the railroad at Fordburg near the Robinson mine. Dozens of people were killed and injured and a large number of dwellings were entirely demolished. The killed and injured were chiefly among the poorer class of Boers and others residing near Fordburg. The mining companies started a subscription to alleviate the sufferings of the injured, and in about 24 hours nearly $200,000 had been subscribed, making a record not equaled for liberality in the civilized world, clearly showing that there were some broad-minded people in Johannesburg. Since the English have been in power the railroad rates under Government management have been lowered about 40% and outside competition is allowed, but the gold tax has been increased from 5 to 10%, presumably to pay the war debt. Owing to the shortage of Kaffirs at the close of the war, the experiment of importing Chinese was tried. They were engaged for three years with their passage paid both ways, and proper arrangements were made for feeding and housing them. They proved efficient laborers, but English sentiment was opposed to time-contract labor, and termed it a form of slavery. There was also some racial prejudice on the part of the Boers. So at the expiration of their time the Chinese are being sent back. The black natives are the natural laborers of the country, and of course are entitled to the opportunity to work on the mines, where they can better their conditions. In their kraals the natives are scantily clad and they have little else but corn meal to eat. On the mines they are well fed and housed in a sanitary manner.

There is no mining centre where the enterprise of capitalists has done as much for the advancement of the mining industry and for the comfort of employees as at Johannesburg. At the present time the Chamber of Mines is offering a prize of $25,000 for the best rock-drill for stoping, and this is open to the world until the end of December. Some of the mines require an expenditure of from $3,000,000 to $10,000,000 for development and equipment and four years' time before they can be put on a paying basis. Capital is still being subscribed for this kind of work, notwithstanding the obstructions put in the way by politicians who send labor agitators and emissaries to stir up trouble; moreover, uniformed religious fanatics 6000 miles away want to dictate to mine managers, who are familiar with the situation, and tell them how they should deal with the native black man at Borea Boola Jar. Others, especially legislators who do not realize that the mines are the main support of South Africa, are inclined to create obstacles, which intimidate the capital that would otherwise be invested for the purpose of developing the millions of tons of low-grade ore that cannot possibly be worked except under the most favorable conditions.

Accompanying this historical sketch there is a tabular report showing the results of operations on the Robinson mine, showing a gross production to date of £7,312,267.

CENEFUGAL DRY CONCENTRATOR.

*At a recent meeting of the Société d'Encouragement, a centrifugal separator for the dry concentration of ores, improved by M. Souchon, was described by M. Lavauden. This apparatus seems to have left the experimental stage. It is employed at the La Faire copper mines, Oisans, and the interesting results obtained have led the El Old Mining Co. to apply it on an extensive scale in their works at Ezazaray, Spain. In the dry process, the difference in acceleration acquired by the various particles, projected with great velocity in a resisting medium, which here is atmospheric air, is brought into play. Crushing for dry treatment should be finer than for washing, and it seems that a maximum diameter of 2 mm. can hardly be exceeded. The crushed ore is conveyed directly to the centrifugal separator. It consists of a cast-iron frame, inside which is a vertical electric motor. There is a circular plate on the induced-coil shaft, and in the centre of this plate there are a number of flanges, while on its circumference there are grooves of a special form, like the flanges, according to the nature of the ore. The plate is covered with a cap with an orifice in its centre, through which the material to be treated passes. This cap drives the material into the grooves and prevents it acquiring an ascensional movement from the great rotary velocity. The motor is governed by two rheostats, mounted so as to assure an exceedingly precise regulation of speed. This is a necessary condition, as the curve of projection of the material, that is, the distance which each particle travels before it falls to the ground, is determined by the combination of the velocity and the weight. The speed of working must be determined by experiment according to the nature of the ore. In treating grains 2 mm. diam. at most, with a speed of 800 to 1200 r. p. m., the maximum trajectory is less than 10 mm. Each concentric zone will contain particles of the same weight, so that a final separation has still to be made. This separation is easily reached by screening to obtain the grain of each particular zone. In principle the smallest grain of quartz deposited should be larger than the biggest grain of ore fallen in the same zone, otherwise screening will not be effective. Practically separation is not as exact as theory calls for, as the rotary motion of the separator causes eddies in the air. There is also the interference between particles. The mineral projected by the separator is automatically collected from each concentric zone and conveyed to the corresponding screen. This collector is a central cast-iron column on which the separator is bolted. On this column there is a boss into which sixteen wooden arms are fitted, carrying scrapers. The ore thus collected falls through openings in the corresponding zone, whence it is conveyed through special ducts to suitable screens. The degree of enrichment obtained by the process varies. In treating crude ore of 0.54% it can be raised to a percentage of 2.5%, and even 10% by a second separation.

CHLORINATION IN CALIFORNIA.

Written for the MINING AND SCIENTIFIC PRESS
By Wilton E. Darow.

The Plattner system of chlorination was first introduced into California at Grass Valley by G. F. Deetken in 1857. The process is said to have been successful from the start, but many of the earlier tailing dumps assayed as high as $75 per ton, and were subsequently purchased, and shipped to the smelters at San Francisco for final treatment. Previous to the introduction of the Plattner chlorination process, the only method employed for the recovery of the gold associated with the sulphide-concentrate obtained in the gold-mills, was to grind and amalgamate them, in various appliances such as araratres, pans, and Chilean mills. As only a small part of the gold associated with the sulphides in concentrate can be recovered by such a crude method, any process that would yield a 75% recovery, would have been considered successful. The process rapidly came into general use throughout the gold mining districts of the State, and it was the chief one used for more than 25 years. Unfortunately, it was introduced as a manual process, using hand-reverberatory furnaces for desulphurizing the ore, and excessive quantities of salt were added in the furnaces for giving a chlorizing roast. For many years 5% of salt was the quantity generally used, resulting in excessive volatilization, and in losses through slaggling.

At that time in Nevada and Arizona many tons of rich silver ores were being treated by roasting with salt, followed by pan-amalgamation. As it was necessary to use large quantities of salt in the furnaces to chloridize the silver, the men in charge of gold-chlorination plants probably thought that their ores also needed salting. Of one thing they were certain: namely, that the gold dissolved easier afterward, and the generation of chlorine gas from chemicals was both disagreeable and expensive. This was also a period when nearly all working metallurgists were in possession of profound 'trade-secrets,' transmitted only in whispers to favored disciples; to men who could be trusted to keep in the straight and narrow rut. In other parts of the world where there were larger quantities of sulphide ores amenable to the process, mechanical furnaces and barrel-chlorination plants were installed, and greatly reduced the working expenses, and increased the extraction of the gold. In California the metallurgists kept wallowing along in the old Silurian rut, until awakened with a jar, to find the smelters absorbing all the available concentrate.

From a careful study of the Plattner process, as formerly practiced in California, it appears that there were losses, some due to mechanical defects in appliances used, others due to ignorance or carelessness on the part of those in charge of the work. One cause of loss is that some of the ore passes through the reverberatory furnace without being thoroughly oxidized. This occasions a loss from the excessive consumption of chlorine during the charging of the vats with gas; and a second and greater loss in the subsequent leaching of the ore, by the formation of precipitants that mingle with the gold-chloride solution, and precipitate some of the gold, leaving it in the tailing. This unoxidized ore is sometimes due to improper roasting, but even with careful attention some ore will pass through a reverberatory furnace in the form of lumps. Some of the lumps are due to argillaceous gangue material, associated with the concentrate, due to imperfect work at the gold-mills, while others are caused by partial oxidation and agglomeration of some of the concentrate. This is particularly noticeable when roasting concentrate that has been stored for several months in a moist condition. Even fine dry salt if charged into a furnace with damp ore will help to bind some of the concentrate into lumps that will pass through the furnace without being broken up and oxidized. Moist or lumpy salt charged into any part of a furnace will form salt-balls, that pass through the furnace encased in a shell of imperfectly roasted ore. To obviate these difficulties it is evident that both the ore and the salt should be dry and pulverized before being charged into the furnace.

Heavy losses are occasioned by the fusion of some of the ore in the furnaces, when applying the finishing heat for the decomposition of the sulphates. When sulphide ores are giving off the first atom of sulphur a high temperature is evolved, which, if slightly augmented by the addition of external heat, will suffice to produce incipient fusion on the exposed surface ore-mass, locking up the contained gold in an impervious slag. Again, when 'dead-roasted' ore combined with salt is heated to a certain temperature, there seems to be a reaction whereby a ferro-silicate of soda slag is formed, effectually locking up some of the contained gold, while the liberated chlorine combines with other atoms of gold and passes off as a volatile chloride. I have made many tests on volatilization-losses, and have never detected them in other parts of a furnace, or found them to occur when sulphates were still present in the charge. For this reason I made a practice of having the finishing heat applied before the sulphates had all been broken up, so that the finished charge when spread on the cooling-floor would still give off a slight odor of sulphur. My later practice, however, has been to nearly dispense with the use of salt in the furnace, obtaining a much higher extraction thereby, but requiring more chemicals to chloridize the ore.

Most of the concentrate obtained from the California gold ores contained some basic elements that may be converted into sulphates by adding a small quantity of sulphuric acid to the water with which the roasted ore is dampened before being charged into the vats, thus rendering them inert to the action of chlorine-gas. In my practice I have found that the addition of about 0.75% of the acid is beneficial in preventing an excessive consumption of chlorine-gas, but the addition of any acid in excess of the quantity necessary to satisfy the bases does not reduce the consumption of chlorine, although it has a marked effect in reducing the percentage of extraction of the gold. The addition of 2 or 3% of acid almost completely prevents the extraction of
any gold. When ferrous-sulphate is used to precipitate the gold from solution, the reaction is rapidly completed as soon as a sufficient quantity of the precipitant has been combined with the solution, but the resulting precipitate is in so fine a state of sub-division that a long time is required for the solution to settle clear. I have found that even after standing 48 hr. before being siphoned off, the waste solutions still contain fine precipitate to the value of about $1.80 per ton of solution. This was formerly allowed to run to waste at many of the plants in California, and represented about $2 per ton on the ore treated.

A hand-rabbed reverberatory furnace is totally unsuited for the purpose of desulphurizing ores, for the reason that it is commercially impracticable to employ a sufficient force of men to rabble the ore often enough to prevent some of it from becoming overheated when applying the finishing fire to the sulphate charge. In Colorado a rotary-hearth furnace gives excellent results, overcoming the difficulty above referred to. The distinctive feature of this furnace is that, as the fire-boxes and rabbles are stationary, while the hearth is constantly rotating, there is no chance for the ore to remain where it receives so high a heat as to fuse it.

A few years ago at the Mount Morgan mine in Queensland a large barrel chlorination plant was discarded in favor of an open-tank leaching process. In this process the chlorine gas is absorbed in water, forming a weak solution that does not give off chlorine when exposed to the air. The leaching is done in large asphalt-lined concrete vats, from which the spent tailing is discharged by steam-shovels. It is said to be the cheapest and best of the chlorination processes. I made a number of tests on California roasted ore and tailing, with this process, and obtained excellent extraction with fuming saturated solutions, while weak solutions, such as are used at Mount Morgan, dissolved but little of the gold. Several years ago an article was published in the Mining and Scientific Press descriptive of a Plattner chlorination plant in Australia. The writer stated that if a sample of roasted ore was saturated with gold-chloride solution, some of the gold would be precipitated in the ore in an insoluble form, and could not be extracted by subsequent ‘gassing’ and leaching, although another sample of the same ore that had not been saturated with the gold chloride would give up its gold readily. I have made tests and find that the statement is correct. For this reason I believe it would be better to destroy these precipitants previously with chlorine gas before commencing to circulate chlorine water through the ore, which would immediately become charged with gold, and, coming in contact with bases, would leave some of it in the tailing.

In a modern chlorination plant the old wooden vats should be replaced by asphalt, or lead-lined concrete vats. These should be built with slightly conical bottoms, and a central discharge for solutions and tailing. Wooden filter-bottoms are a nuisance, and should be avoided. A good filter may be constructed of perforated stoneware and coarse sand. Wooden covers may be employed, and these should fit into water-sealing grooves in the top of the vat. The chlorine gas should be generated electrolytically from common salt, and could be charged directly into the ore-charged vats as fast as needed, while at other times it could be sent to a scrubbing tower, and formed into a saturated solution for leaching the ore in the vats after they had been first saturated with gas. Any gas displaced from the vats by the leaching solutions could also be sent either to other ore-filled vats, or to the scrubbing tower, thus converting what is generally a nuisance around the Plattner plants into a valuable reagent for the recovery of gold. I think the excess of free gas could also be recovered cheaply from the gold-chloride solutions before precipitating the contained gold.

Water absorbs a maximum quantity of chlorine at a temperature of about 50° F., and gives it all up at 212°. If the solutions were heated in a closed receptacle to a temperature of about 100° F., the boiling point could be lowered by means of an exhaust fan sucking out the chlorine gas as fast as it escaped from the solution, and forcing it either into a vat of ore, or else to the tower for making up solutions. Where gold has been precipitated in a Plattner chlorination vat from the precipitating action of unchloridized sulphates a wash with a saturated solution of chlorine water is effective in dissolving and recovering it. Therefore I think it should be used as an adjunct to the Plattner process. In an up-to-date plant all ore and solutions would be handled mechanically, making it cheaper than the present barrel process, usually estimated to cost about $3 per ton of ore.

The Greenawalt process, applied in Colorado and Nevada, offers some exceptionally interesting innovations that may be useful in treating California products. Briefly stated, it consists in roasting the ore in a mechanically rabbed muffle-furnace, using a heated air-blast which is introduced under the furnace-hearth. The roasted ore is cooled, charged into leaching-vats, and leached with a saline chlorine-solution, forming by taking up electrically generated chlorine-gas in a scrubbing-tower with a saturated solution of salt water. The solution has the power of dissolving silver, lead, and copper, as well as gold. The solution is then precipitated electrolytically on lead shavings for the recovery of the gold; after which the solution is electrolyzed, re-generating the chlorine for future use, and recovering the other metals.

Since the discovery of diamonds in a peridotite dike in Pike county, Arkansas, energetic search has been made for additional occurrences of this igneous rock. The result has been to reveal another outcrop 2½ miles distant from the first-known locality. No diamonds have as yet been found in the second outcrop of peridotite. These igneous masses are evidently the upper portions of a great magma which in a few places has lifted cretaceous strata into domes, and less frequently has penetrated them. Such disturbances, in which, however, the underlying magma did not reach the surface, are common over a large area in Arkansas, and are found even as far south as central Louisiana.
EDITORIAL.

SMELTING OPERATIONS at Ely are fairly under way. In October the Steptoe Valley concentrator and smelter produced 2,000,000 pounds of copper. The concentrator has two complete units engaged, with a combined capacity of 3200 tons per day; a third unit will be completed within six weeks, and work on a fourth unit has been commenced. The smelter has a capacity of 3,000,000 pounds per month and the plant is eventually to be increased so that it will produce 5,000,000 pounds of metallic copper. The concentration is in the ratio of 7 to 1 and the ore is averaging 3 to 3 1/4 per cent copper.

FROM THE published accounts of the annual meeting of the Camp Bird Company we note that Mr. J. E. Spurr was engaged to make a special investigation of geological conditions with a view to giving advice concerning future explorations. It appears that he is opposed to further development work in depth and recommends lateral exploration instead. What knowledge we have of the locality is such as to confirm the correctness of this suggestion, and we congratulate Mr. Spurr on the courage required to give advice usually deemed unpalatable by mine operators. The geologist or engineer who suggests further development in depth can at least be assured that his recommendation will be acceptable to the management and that it will not be proved incorrect for several years, if at all, for 'depth' is a beautifully vague limit, which, like the feasts of the Church, can be moved. Lateral development is much cheaper than shaft sinking and in a region traversed by a complex system of vein-fractures it is more likely to lead to the discovery of ore.

WITH PLEASURE we learn that Mr. Henry A. Miers, professor of mineralogy in Oxford University, has been appointed principal of the London University. His book on mineralogy is known to students and his personality, we are told, is as attractive as that volume. Possessed of energy and initiative rare in "the home of lost causes," Professor Miers is also an effective lecturer and a good administrator. Service on numerous committees of organization for technical institutions in many parts of the world has given him an experience that should prove useful now. Born in Brazil, instructed at Eton, educated at Oxford, and a traveler to many regions, he is a man of broad sympathies. Among his travels may be mentioned those to South Africa, British Columbia, and the Yukon, as likely to give him an understanding of mining affairs. He is old enough to have poise and young enough to retain enthusiasm. We welcome his appointment to the head of the University of London because the Royal School of Mines is now tied to that educational institution.
With such a Principal, the old R. S. M. ought to do well.

CHAFEY is the latest of the old mining camps of Nevada to be revived by the breath of up-to-date industry. Under 'Special Correspondence' we publish an interesting letter from a correspondent, Mr. Aubrey L. Wisner, who writes both carefully and well. We wish good luck to this new-old district.

SPELLING REFORM suffers more from its friends than its enemies. In a letter sent out from the Smithsonian Institution by Messrs. R. S. Woodward and L. O. Howard, it is stated that the American Association for the Advancement of Science has become a clearing house for the scientific activities of America and offers membership without entrance fee to those who are members of certain technical societies. With that we do not quarrel, but then we note that a letter signed by two scientific men of prominence under the auspices of the Smithsonian Institution and the American Association contains such mongrel spelling as thrè for 'through' and cheque for 'check'. We have received a protest from a member of the American Institute to whom one of the circular letters was addressed. We are in accord with him. Thrè is the 'funnetie' spelling, while cheque is antiquated. Anyone adopting thrè while retaining cheque shows himself the victim of a fad, not the intelligent supporter of a scientific departure.

WE NOTE with pleasure that the premier mine of America, the Homestake, continues to be profitably productive. An abstract of the report for the fiscal year ending on June 1, 1908, appears on another page. The mills treated 1,450,900 tons yielding $4,717,746, or $3.25 per ton. Operations were affected by the fire that stopped the extraction of ore during a portion of 1907 and, as far as we can deduce from the statement of accounts, the profit for the period under review was $1,107,282. A dividend of $546,000 was distributed. The report is not conventional in form, but it scarcely calls for comment, as the mine is controlled by Mr. James B. Haggin and the representatives of the estate of his deceased partner, George Hearst. It is to the Homestake that the University of California owes, at least in part, the munificence of Mrs. Phoebe Hearst, the widow of the man who was closely connected with the early development of this great mine. No particular mention is made in the report concerning the new cyanide annex. It is generally understood that this plant, designed by C. W. Merrill, the consulting metallurgist to the Homestake Mining Company, has proved a notable success, and that approximately one-half the profits are due to the extra gold saved after the stamp-mills have done their best.

FEAR that an increased production of cheap copper to come from the big mines at Ely, in Nevada, and Bingham, in Utah, would tend to depress the market price of copper should be lessened by the recognition of the fact that new producers are not numerous. Although 25-cent copper, while the price lasted, did greatly stimulate the search for new mines all over the world, it is noteworthy that on the American continent only the Miami and the Ray appear to have been added to the list of those likely to be heavy producers. The Cerro de Pasco, concerning which we publish a valuable article by Mr. Lester Strauss, was started before the copper boom, and the bonanza deposits of the Copper River, in Alaska, were known before high prices spurred prospectors to feverish seeking for new deposits. While the 8 and 9-cent copper of the 'disseminated in porphyry' type at Bingham and Ely will furnish a large production, it is reasonable to expect that it will be absorbed by domestic consumers in case of any such industrial revival as is confidently expected. Use of copper in the electrification of railroads is sure to be a big factor in creating a market for the metal, and the chief obstacle to such an employment of copper would be an abnormal price. A 14 to 17-cent quotation is more likely to aid the best interests of mining than the 20 to 25-cent price prevailing in the early part of 1907.

Votes Lost.

Election day is over, and the returns indicate that most of us are pleased with the result. All of us are glad that the dust-storm of political activity is past. It is too early to make general deductions, but we shall hope to do so when an accurate analysis of the vote has been made. In the meantime there is one aspect of the election that invites immediate comment. We refer to the large number of professional and business men practically disfranchised by the necessities of their vocations, whereby they were compelled to be absent from home on election day. Among these it is fair to say were some of the most intelligent citizens of the country. For instance, the number of passengers carried on the railroads of the United States during 1907 was 860,648,574, and the passengers traveled an average of 32.72 miles. While the population is 84 millions, the voters total 14 millions, so that only 1 in 6 of the population is a political unit. The average number traveling on a single day is 2,350,000, and of these more than 1 in 6 would be voters, because women and children travel less than men, but fully one-half the passengers would be making short journeys such as would not interfere with their electoral privilege, so that, on a rough estimate, we infer that 400,000 men lost their vote. Some of these failed to register, not expecting to be at home on election day. But even a smaller number—say, 250,000—is enough to be an important factor in some elections, either State or National. Apart from the loss to either party of a large number of votes, there is the denial to the individual of his privilege as a citizen. Some men travel on election day from choice, but the majority are under orders from their employers or else they are moving in the performance of industrial functions. There is a remedy. Identification by signature is recognized in business affairs; in the elections of societies and associations, voting by mail is deemed safe and proper. Why not adopt a letter ballot with a perforated slip wide enough for a signature, somewhat
after the style of a bank check? The Congress should enact a law by which a properly registered voter, compelled to be away from his precinct on election day, could vote by mail. Among those entitled to the right, but losing it by the discharge of duty, are railroad and steamship employees, commercial travelers, and professional men—especially those nomads, the mining engineers.

State Mining Bureau.

In our issue of February 8 we criticised the administration of the Mining Bureau and explained how it was prostituted to political service. We said little concerning the State Mineralogist, who is the chief of the Bureau, for we regard him as an accidental and ephemeral feature in the political corruption of California. At that time we protested against the summary dismissal of Mr. Charles G. Yale, who as statistician had for many years given the Bureau a dignity it otherwise wholly lacked. The resignations of three of the trustees—Messrs. Curtis H. Linder, F. W. Bradley, and E. A. Stent—was recorded, and the hope was expressed that the two remaining trustees, Messrs. Louis Janin and Harold T. Power, would refuse to lend themselves further to the farce enacted in the Ferry building. Shortly afterward we were informed authoritatively that steps had been taken to invite Mr. Yale to resume his duties, and that our silence on the subject would facilitate an adjustment of the difficulty. We learn now that Mr. Aubury tricked Mr. Yale into an impossible position, and the net result is that the Mining Bureau has been made even more ridiculous than usual, for the newspaper reporter who replaced Mr. Yale as statistician has collaborated with Mr. Aubury in publishing statistics that are infantile in their incorrectness. According to the Bureau, a gain of nearly $9,000,000 was made by California in the value of the output of 1907 as compared with 1906. This would be gratifying were it even approximately correct, which it is not. Fortunately, the experts of the Geological Survey furnish figures for comparison: these are available in the ‘separates’ or advance chapters of the annual report of the Division of Mineral Resources already hand. While recognizing that statistics are necessarily subject to error, because of the difficulty of compilation, and that even the Survey has published statements open to criticism, nevertheless, we know that the specialists employed by the Government are, in the main, both careful and competent, while, on the contrary, we know that Mr. Aubury and his present arithmetician are both careless and incompetent: therefore we presume that any glaring discrepancies between the two sets of figures are properly to be imputed to the incompetence of the newspaper reporter placed by Mr. Aubury in the position filled so long and so faithfully by Mr. Yale, a man of national reputation in the domain of mineral statistics. But there is other evidence of error, besides the deadly parallel with the Survey’s reports. For instance, the Bureau gives 164 tons, valued at $16,690, as the output of lead, while it is a fact that one company in the county of Inyo smelted ore from which 1068 tons of lead was obtained. Although there is so little coal mining in California, the Mineralogist was unable to make a good guess as to the production. He says the State produced 23,734 tons, worth $55,849, while the Survey shows that only 13,590 tons, valued at $38,213, were mined. The representatives of the Survey visited the coal mines while the Mineralogist was engaged in preparing self-laudatory articles for the daily press. He guessed the output of gums to be worth $232,642, when it was $165,010. He found that $2,270 tons of pyrites had been mined, while the Survey returns show only 51,350 tons, with a proportionate difference in total value. He finds 300 ounces of platinum worth $20.84 per ounce, when there was not much over 100 ounces, which sold at $15.50 per ounce. The highest price paid was $17 and the lowest $14 per ounce. The Bureau credits California with only one ton of manganese, worth $25 per ton, while the Survey returns 100 tons, valued at $6 per ton. In mineral water, the Bureau gives nearly 3,000,000 gallons, valued at $544,016, but the Survey shows only 1,080,169 gallons were produced, with a valuation of $400,572. The basis of valuation must have been wrong in one of these estimates. In copper, the Mineralogist has blundered to the extent of about 4,000,000 pounds in quantity and $600,000 in value. He credits Siskiyou county with 27,844,364 pounds, while there is good reason to believe that the output was less than 23,500,000. He probably got his smelter and refinery figures mixed with the mine returns. This is a common blunder of amateur statisticians. Moreover, the Mineralogist is short over 400,000 pounds in the Calaveras output, and in his tabulated statement he says that the output of Kern, Humboldt, and Mariposa counties may be found among the ‘unappropriated’, but he gives no unappropriated figures for copper. He appears to have adopted the smelter returns of California copper as given by Mr. L. C. Graton of the Survey; these are much larger than the mine returns, but the Mineralogist did not know the difference. In other substances the discrepancies are no less striking: thus the Bureau puts the granite output at $573,376, while the Survey has $1,306,324. The Survey values the limestone (not burned into lime) at $177,332, and the Bureau places it at $406,041. The Survey has a valuation of $1,029,749 for trap-rock in 1907, but the Bureau makes no mention of this product, although it probably figures as ‘maeadam’. The Survey’s total for granite, trap-rock, sandstone, marble, and limestone is $2,254,026, while the Bureau gives the combined value of the granite, limestone, maeadam, marble, paving blocks, rubble, and sandstone at $3,159,995. It is not necessary to go into further details. Enough has been said to prove the absurdity of these so-called ‘statistics’ of the State Mining Bureau.

The statistical sheet giving to the world the proof of the maladministration of the Mining Bureau is the only publication issued by that office for more than a year, notwithstanding the employment of several persons supposed to be engaged in useful labor. While the Mineralogist is not expected to
originating anything of technical or scientific value, having had no training for such work, it is supposed that he would engage people who could do something of the kind. He did attempt to collect the gold and silver statistics for the past year, but failed to do so, and was finally compelled to take the data prepared by the resident official of the Geological Survey. In spite of this fact, Mr. Auburly failed to credit either the Survey or its representative for the figures used. Until a man of character occupies the office of State Mineralogist it is a waste of the State’s money and a slur on the State’s reputation to attempt the compilation of statistical information.

The Mining Bureau as now conducted is a gross impertinence; it is subject to the management of a nondescript assayer who is the beuchman of a political boss of the railroad company that has debauched the public life of California for the time of a generation. There is a Board of Trustees, but the members of it serve merely as an auditing committee giving their sanction to the money expended by the Mineralogist. We call upon the trustees—Messrs. Louis Janin, Harold T. Power, Frank Griffin, A. H. Ward, and C. T. Deane—to stop the farse in which they are playing a discreditable part. They know the meaning of the expression. It is their duty to the State to separate themselves from the Bureau and to protest against the stultification of the mining industry. At present they act as an auditing committee, with no real power to discipline or improve the work of the Bureau. By remaining in office they condone the degradation of a State institution; by resigning and using their influence in the community and before the Legislature, they can hope to do some good.

If the Bureau is to continue to be an appanage of the Southern Pacific, let it be abolished. It serves no useful purpose now. The museum and the library might be placed in charge of the University.

At this juncture we are reminded that there is a California Miners Association. It is moribund; it has failed to meet since 1906; even the executive committee has not been called in session for nearly a year. Here is a live issue. The Association could do nothing better than devote itself to the re-organization of the Mining Bureau. Let the public opinion of the State be aroused with a view to bringing such pressure on the Legislature, when it convenes early next year, that legislation may be enacted either mending or ending the Mining Bureau. The State Mineralogist should be appointed, not by the Governor, who is usually a political puppet, but by a Board of Trustees, chosen on non-political grounds by representative organizations such as the Faculty of the University, the Miners Association, the Chamber of Commerce, and the like. The Board, once selected, should be self-perpetuating, after the manner of the Public Service Commission in New York, and the man chosen by them for State Mineralogist should hold the appointment for life, or as long as he remained competent. If a reasonable salary be paid and a proper appropriation set aside for the service of the Bureau, it could be made worthy of the great mineral industry of the State of California. At present it is a pitiful absurdity.

Personal.

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

T. LANE CARTER is here.
WILLIAM A. FAIRISH is at El Paso.
F. W. BATES is expected at New York.
A. CHESTER BARTY in New Mexico.
HENRY BURBIDGE is on his way to Manchuria.
F. F. SHARPLESS has gone to London from New York.
O. B. PERRY has returned from Dawson to New York.
EDMUND JENSEN has returned from Nevada to Spokane.
W. L. LEWIS has arrived in San Francisco from Nome.
RUXE PROUST is at Kuala Lumpur, in the Malay Peninsula.
CHARLES W. GOODALE has returned to Butte from New York.
CHESTER A. THOMAS has returned to Santa Barbara from Dawson.
FRANK OLDFIELD is visiting San Francisco from Los Angeles.
THOMAS COX will be returning from Cerro de Pasco in February.
T. R. DRUMMOND is manager of the Cactus mine, at Newhouse, Utah.
THOMAS G. DAVEY has an office at 210 Finsbury Pavement House, London.
JOHN C. F. RANDOLPH has returned to New York from a visit to England.
CARR. HENRY is manager for the Mineral Development Co., at Guanajuato.
GEORGE L. SHIELDS, of Denver, is operating at Badinguato, in Sinaloa, Mexico.
L. I. OGDEN has returned from Korea to his home at East Aurora, California.
W. F. HARRIS is manager for the Inde Gold Mining Co., in Durango, Mexico.
HUGH R. VAN WAEGHEN is in San Francisco on his return from Valdez, Alaska.
E. W. PARKER, of the Geological Survey, is investigating the coal mines of California.
THOMAS J. RICKARD has been appointed assayer at the St. David's gold mine, in North Wales.
HENRY F. LEYFHAL has been examining the Big Halstead mine, in Plumas county, California.
J. M. MOWERAY has returned to London from a visit to the lead mining districts of Missouri.
ALEXANDER LEGGAS has returned to Butte from a two months surveying trip in eastern Montana.
CHARLES W. ABERT is at Ely, Nevada, having resigned a position on the Daisy mine, Goldfield.
JAMES MOFFET, of Oakland, California, has gone to Colina, Mexico, to examine deposits of iron ore.
W. F. FENNIX has been appointed mining geologist to the United States Smelting, Refining & Mining Company.
CHARLES M. BECKA resigns as manager of the Stratton's Independence mine, Cripple Creek, on December 1.
C. D. GROVE has taken charge of the Skagit Queen Con. Mining Co.'s operations at Marblemount, Washington.
C. W. PURDINGTON writes from the Ohotea district, in Eastern Siberia, but he expects to be in London shortly.
JOHN A. REID has gone to Phoenix, Arizona, to recuperate from an attack of malaria, contracted in Lower California.
F. G. CLAPP is spending the greater part of the fall examining oil and gas lands in Pennsylvania and West Virginia.
DELILH HARVEY & FELL have been appointed consulting engineers to the Cobar Gold Mines, Ltd., in New South Wales.
H. S. Mulliken, superintendent of the Peboles smelter, at Mapimí, Durango, Mexico, is spending a vacation at Los Angeles.

T. T. Barnard, connected with the Pacific American Mines Company, will soon go from Gold Hill, Ore., to Mettawa, Washington.

George E. Howard, general manager for the Sahayaean Mining Co., at Oceana, Chihuahua, has returned from Pittsburg.

James J. Hollister has been appointed assistant general manager for the Hinde Co. Mining Co., at Santa Barbara, Chihuahua.

Walter L. Brown, who was recently in charge of cyanida experiments at the Alaska-Treadwell mine, has gone to South Africa.

Eunice E. Haggott, of Los Angeles, has returned from Alamos, Sonora, where he is directing work at the Santa Domingo mine.

M. T. Gibson has resigned as local manager for the Wild Goose Mining & Trading Co. at Nome and will operate on his own account.

C. M. Eye, superintendent of the Benguet Consolidated at Baguio, P. I., is visiting points of interest along the China coast and in Korea.

Walter L. Ehricke has resigned as superintendent of the Bonanza Belt Copper Co., at Johnson, Arizona, and has moved to New York.

Walter G. Perkins, smelter superintendent for the Nevada Co. Copper Co., is taking a short holiday on the coast of southern California.

Bertiam Hunt has gone to Alexander City, Alabama, to conduct metallurgical tests for the Hillace Gold Mining Co. He will proceed thence to Mexico.

F. W. Harmon has entered into partnership with Edward Riley, and the firm of Edward Riley & Harbord will have offices at 15 Victoria street, Westminster, London.

Arthur Feust has resigned as manager for the Standard Con. Mining Co. at Bodie, California, and has succeeded by W. H. Langs., of San Francisco.

Cecil Pocock, formerly with the Santa Fe Gold & Copper Mining Co., has recently been appointed general manager of the Montezuma Mines, Inc., with mines at Montezuma, Costa Rica, Central America.

R. W. Ebsco, acting director of the Geological Survey of Canada, has been on an official visit to the Sicuan district, British Columbia, where W. H. Boyd and O. E. LeRoy, members of the survey staff, are preparing to make a geological survey of the district.

Obituary.

William Carsek died at his home in Los Angeles on October 21. He had suffered from a complication of diseases, the principal being asthma. Born in Cornwall, England, in 1856, he became a resident of this country in 1877, engaging in mine and mill work in Colorado and Idaho. There were four brothers in the family and all of the brothers were interested in the milling of ores throughout their lives, their field of work being Colorado, Idaho, and Montana. In 1883 William Carsek became superintendent of the concentrator for the Colorado Mining Co., at Butte, Montana. He remained faithful to this company for 19 years and became a local authority on practical concentration. His health failed in 1902. It is the opinion of many that his lungs became congested with small particles of minerals of which he sought southern California and then Arizona for relief. While in Arizona, in 1904, he still maintained strength enough to design and erect the Shannon Copper Co.'s concentrator. His wife accompanied him throughout Arizona and in 1904 they took up their residence at Los Angeles. In 1907 he resolved to make a trip to Montana, to see if it were not possible to recuperate in a colder climate. This trip proved disastrous, hastening his death.
General Mining News.

ARIZONA.

CONCISE COUNTY.

It is said that the Shattuck-Arizona is planning to erect a smelter and expects to soon be a shipper of high-grade ore. The shaft is 335 ft. deep, the deepest level being the 300. A body of good sulphide ore has recently been opened up on the 600-ft. level and prospects seem bright. Shattuck-Arizona occupies the highest elevation of any copper producer of Bisbee.

MOHAVE COUNTY.

Two carloads of machinery for the Arizona Gold Mines Co., which is soon to have a 10-stamp mill in operation on the Bi-Metal mines, have arrived, and the mill near Kingman is expected to be in operation within 40 days, and will be equipped with electric lights and every labor saving device known to the business. The plant will be built with a view to increasing it to 100 stamps. A spur track is to be in put for the use of the Company by the Santa Fe and the work of grading is now in progress from a point above McCunnico.

FINA COUNTY.

It is reported that the Benson group of 14 claims, in the Ray-Kelvin district, has been taken over by the Ray Consolidated and that negotiations are under way for acquiring the Kelvin Calumet. The Ray mill is to be started soon.

TAYLOR COUNTY.

(Special Correspondence.)—Three shifts of men began work last week sinking the shaft of the Big Stick mine at Santa Maria. This is one of the properties belonging to the Manhattan Securities Co., of New York, and is under the management of Lloyd C. Haynes, president of the Company. Mr. Haynes is making arrangements for developments on a much larger scale than heretofore, which includes the erection of a 50-stamp mill. Plans are formulated for the sinking of the present shaft 1900 ft., cutting stations at intervals of 100 and 200 ft., and to this end machine drills have been placed in operation. The other property belonging to the Manhattan is the Haynes copper mine, at Jerome. Developments on this property are very encouraging, and work is being pushed with vigor. The Company has expended over $900,000 in development work and in the purchasing of machinery the past year. The Mikado mine, in the Eureka district, has recently found a streak of ore three feet thick, assays from which average about 100 oz. silver, 10% lead, and some gold and copper. This find was made in the breast of an adit which is 312 ft. long.—E. B. Van Deman is preparing to start work on his McCullar group of claims in the Weaver district.

PHOENIX, October 21.

Yuma County.

The Crackerjack claims, 12 miles southwest of the North Star and King mines, have been banded to a group of Los Angeles capitalists for $250,000. The property was located only five months ago, and since then a 500-ft. shaft has uncovered ore averaging $75 in gold. It is said the new company intends to build a mill.

California.

NEVADA COUNTY.

(Special Correspondence.)—Some time last Wednesday night thieves looted the vault at the North Star assay office and carried off a considerable quantity of precipitate from the cyanide plant. The crime was one of the boldest ever committed in this city.—Tunnel No. 7 at the South Yuba mine is being pushed steadily and is expected to cut the orebody within a short time. It is 600 ft. below the old workings and will give about 1200 ft. of backs. The company expects to erect a 50-ton smelter as soon as sufficient ore has been developed. The main orebody has been penetrated for 50 ft. with no sign of the opposite wall. The mine is a copper proposition. Max Martinette is superintendent.—The Conlan M. Co. is liquidating a number of its local debts, and it is thought that the property will resume operations in the near future.—Charles Cole and Williamson Bros. have filed a suit in the Superior Court against the Washington M. & D. Co., involving title to the Red Ledge mine in the Washington district. A demurrer has been filed by the defendants.

Grass Valley, November 2.

San Bernardino County.

Hart & Hitt have sold their Oro Belle No. 1 and No. 2 claims, at Hart, to a Philadelphia company for $100,000. The Eastern concern is represented by A. B. Hall, who has now gone East to complete final arrangements. It is said that on his return, in three weeks, 75 men will be started in the mine and that a large stamp-mill will be erected. A nominal cash payment was made and a large installment is due within 30 days.—It is reported that the Big Chief Mining Co., of which George A. Foster is president, is considering the building of a stamp-mill on its property near Hart.—The working force at the Jumbo has been practically doubled during the last week. The work is centered on driving on the 100 and 200-ft. levels, the showing on the latter being particularly encouraging. George B. Wilson, of Searchlight, is superintendent.

Shasta County.

Indications of oil have been found in drilling an artisan well about two miles east of Anderson. The well is 190 ft. deep and the water is said to bring up considerable oil. A small crew of men is employed in working the Summit mine on Little Backbone creek. The shaft, which is following a clay gouge, is at a depth of about 150 ft. below the level of the adit, giving a total depth from the surface of about 300 ft. Although no great strike has been made, conditions are very encouraging. An electrically operated compressor furnishes air for drilling, hoisting, and pumping.

Sierra County.

A San Francisco company, headed by J. J. Crawford, has homed the claim near Lucky Dog ravine which belongs to Bixby & Son. The new concern will start work at once.

A complete equipment of electrical mining machinery is being put in on the No. 4 level of the Crossen mine at Plumas. The lower adit will be extended 5000 ft. and will then strike daylight on the Kanaka Creek slope. Pending the completion of the new power plant, all of the

Map of California.
The owner, has been in the district for several days and has formulated plans for continued work. Driving will be started in the upper workings. This property was a former heavy producer of silver, gold, and lead ore.

The Memphis & Idaho Springs Co. will resume work at once on the properties owned on Section Mtn. The Company has just been re-organized and funds raised for an extensive campaign of work. Driving will be started on the vein that has been intersected by the bench, which is Woodruff & Malone, of Denver, have been appointed representatives of the new organization. The plant of machinery for the Merry Monarch M. Co., operating in the Alice district, arrived last week and is now being transported to the mine. — H. L. Williams, leasing on the Specie Payment, has shot into a 16-in. streak of smelting ore that is estimated at 95 d. per ton. — J. W. Smith, of Dumont, reports that he expects to have the property of the E. S. James Co. in shape for producing in the near future. The showing is improving from day to day and there is a stenk of $40 ore in the breast of the adit that is from 9 to 15 in. wide. Within the next two weeks extensive development will be started at the Smuggler mine on Brown Mtn. In addition to deepening the shaft 75 ft., the east and west drifts on the property will be extended. The Longfellow at Sonora has been sold and that operation is to be started at once.

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence.) — Work has been resumed at the adit on the Key West property, on Leavenworth Mtn. The first vein to be cut is the Key West, which should be reached within 100 ft. From shaft workings ore was mined a number of years ago that milled as high as 2 oz. gold and 150 oz. silver per ton. The property has been secured under bond and lease by E. Butts, who is now forming a company composed of Minnesota capitalists. A plant of machinery is to be put in at an early date to facilitate the work that has been planned. Shipment will be started next week from the Drummond mine on Colorado Mtn. During the past few weeks work has been in progress and a streak of ore has been followed for over 200 ft. that is from 10 to 14 in. wide, the average content being about $40 per ton in silver and lead. Slaking has been started in the bench where the width is over 90 ft. and the mine is being named the Spotted Fawn above Columbia. It is reported that the Longfellow at Sonora has been sold and that operations are to be started at once.

MINING AND SCIENTIFIC PRESS

November 7, 1908

mines underground have been laid off except four, but a force of 20 men is employed in the construction work. As soon as the new plant is finished, which will be about Thanksgiving time, the regular force of 50 miners will be reinstated. W. W. Mather is manager and W. H. Sebley, of New York, is president of the Crossen G. M. & M. Company.

SIKITUO COUNTY.

A company of San Francisco capitalists, headed by V. G. Bonaly, has purchased the Swanway and Forest properties on the North Fork of Salmon river. Work is now under way on a four-mile flume to carry the water to the claims. John Fehely and P. L. Young have charge of operations.

Other properties on North Fork are getting things in shape to start sinking and indications are good for an active season.

YUOLUMNE COUNTY.

McCormick & McPherson have received a new Hunting- ton mill for their Free Gold property near Jacksonville. Robert Fitzgerald and others, of Quartz Mountain, have bonded the Water Lily placer, near Reynolds Ferry, to Wingfield Sheekler, of Oroville. He will test the ground by drills and if it shows indications worth attention he will dredge it. Thirty of the sixty stamps are dropping at the Harvard. — The Hazelhill, near Italian bar, is being unwatered, and the owners intend to start development. Claims have been named at the Spotted Fawn above Columbia. — It is reported that the Longfellow at Sonora has been sold and that operations are to be started at once.

The Independent District Consolidated Mines Co. has recently been incorporated at Leadville and will at once take up the work on the Berdella and Rosse adits which was started last summer by a Kansas City concern. Joseph A. Lamping is president. The Berdella is already in the mill a distance of 310 ft. and a force of men is now at work under direction of the new company. W. C. Davis, a stockholder and director in the concern, is superintendent. The Rosse, formerly known as the St. Kelvin, is in Sow- belly gulch and has been worked with varying success for some time. The hene is now in 600 ft. and a contract is to be let at once for another 2000 ft. The St. Kelvin was developed as the St. Kelvin vein. — placer mining on the Cache creek, in the southern part of the city, is at an end for this season. The recent cold has compelled all operators to close down. It is estimated that nearly $100,000 has been mined this year.

OURAY COUNTY.

R. W. Clinton, superintendent of the First National group of claims near Ouray, is authority for the statement that as soon as the blower is installed in that property a systematic plan of development will again be resumed. The title to the property rests with the First National Co-Operative Mines, of which the officers receive no salary and the miners own a large part of the stock. Daniel George, of Denver, is president. The group consists of 75 acres on the slope of Mt. Hayden.

SUMMIT COUNTY.

The Cochran property, operated by the owners of the Wire Patch mill, was started last week with electrical equipment. A compressor has been placed in commission, and one drill will be used until progress is fairly started, after which another drill will likely be added. It is proposed to push the adit as rapidly as possible under this arrangement. A large orebody is in sight which will be treated at the Wire Patch mill.

TELLER COUNTY.

The control of the Pharmacist Con. M. Co., operating in the Cripple Creek district, has passed to A. J. Halter and associates of New York. Mr. Halter has been elected presi- dent and J. S. Edwards, of Cripple Creek, will be man-
MINING and SCIENTIFIC PRESS
November 7, 1908.

AGER. The policy of leasing the holdings will be continued and several new applications have already been received.

—The Union Leasing Co., lessees on the Gold Dollar Co. estate, shipped twenty-seven cars of ore during the month of October. Most of the ore came from a slope above the 400-ft. level. Sinking will soon be resumed in the shaft.

DRIFFLE. Blankenship and associates, leading the Tiwalkas, a fractional claim on the southwestern slope of Beacon hill, have purchased the machinery on the Flying Cloud on Bull hill and have contracted for its transportation to the Beacon Hill property.

IDAHO.

IDAHO COUNTY.

James Hand, a pioneer miner in the Northwest, has bonded the Hand group in the Big Creek district, 35 miles south of Grangeville, Idaho, for $125,000, and has cleared the title to the property, which consists of 15 claims. He has exposed a vein of from 90 to 300 ft. wide between well-defined walls of slate. The ore is of a millling quality, running from $6 to $8 per ton. There are stringers of ore in the mine that assay from $200 to $300 in gold per ton.

—Eastern capitalists have bonded 160 acres of dredging ground in the Elk City district owned by the Mas-sam Bros., of Spokane, and will put in a dredge, capable of handling 2500 yd. of gravel per day. The Eastern men have expended $2500 in exploring the property, and are so well satisfied with the showing that they will at once proceed with their plans of development. The first payment of $5,000 will be made November 15, which will leave a balance of $35,000, to be paid in installments.

NEZ PERCE COUNTY.

Final shipments of bullion for the season are being made from the camp at Pierceo, and the gold properties alone have shipped $75,000, which is an increase of $10,000 over last year. The new 15-mile railway road built by the Oxford Copper Mining Co. from Pierceo to the holdings of the Company on Elk creek has been completed. A hoisting and pumping plant will be installed in the near future, and work on a double-compartment shaft to a depth of 300 ft. will soon be completed.

SHOSHONE COUNTY.

(Special Correspondence.)—About eight feet of good carbonate ore of shipping quality has been opened up in the drift on the vein in the Black Bear mine. This drift has now attained a depth of about 1200 ft. and there is every indication that the ore-shoot proper may be broken into at any time. The claims of the company adjoin the property of the Helenia Frisco mine on the east. A contract for $500 has been let to the Valentine company. Claims have been staked to Andrew Jacobsen. The drift in the property has already been run about 500 ft. and it is expected that the ore-shoot may be broken into at any time.

—The Montana Standard mine, on Prospect creek, has been compelled to curtail its production on account of the want of facilities for ore storage, all the bins being filled to their capacity. A large amount of first-class shipping ore has been stowed, and shipments of this will commence as soon as enough snow has fallen. The directorate of the company is at present considering the advisability of erecting a concentrator to handle the second-class ore.

—The new hoist has been installed on the property of the Anchor Co., in the Burke district, and sinking on the orebody has again started. The hoist is designed to sink to the 300-ft. level, to which depth it is proposed to sink and then drive to the vein. About $15,000 worth of ore has been blocked out during the recent operations.

—The Coeur d'Alene Mining Co., which owns 2800 acres of patented placer land in the Murray district, intends to install hydraulic machinery and work the property extensively next year. The Company worked in one pit in the bed of the creek this year, but owing to the rock is uneven and the rocks were too heavy for the eight-inch elevator to handle, the experiment was not successful. It is probable that the Company will install machinery on Pritchard creek to handle the ground, the rock being stacked on the side hill, permitting the bedrock, which is a hard quartzite, to be hand cleaned.

—Judge Frank S. Dietrich, of the U. S. Circuit Court for the district of Idaho, Northern Division, has ordered that the judgment entered in favor of the plaintiff, November 1, 1905, in connection with the suit of James L. Safford against the Bunker Hill & Sullivan Co., for $7000 be vacated and set aside. Safford had an agreement with the Bunker Hill company for working the tailing from the mill in the creek, and claimed that by the acts of the Company he was prevented from working. A contract for 250 ft. of adit work has been let to John Backlund, of Burke, the work to be done on the property of the West Hecla Mining Co. This adit has already been driven about 150 ft., and it is thought that the last contract will be more than sufficient to carry the work to the vein. Heavy stringers of ore, some of which are as much as 15 in. wide, are appearing in the face of the adit. A judgment has been issued in favor of the plaintiff in the case of A. D. Gritman against the Charles Dickens M. & M. Co. The suit was brought for the recovery of about $55,000, the larger part of which is secured by a mortgage over the Company's property. Other suits to the extent of $40,000 are still pending against the property. Considerable feeling has been stirred by these suits by disappointed stockholders, many of whom had regarded the mine as one of the most promising in the district. A meeting of the brokers of Spokane has been called to take action in this matter and an attempt will be made to save the individual stockholders. The business of the Company cannot be settled by means of assessment or otherwise and at the same time change the management.

Wallace, October 31.

KANSAS.

CHEROKEE COUNTY.

(Special Correspondence.)—The Henskin mine, northwest of the old Galena camp, has been recently opened up and a rich ore deposit is being worked at 75 ft. The ore was worked out in drifts under the M. & T. railroad tracks and at this point the mine caved. Since that, the company has been engaged in strengthening the ground to re-open it. A company on an adjoining lot is sinking a shaft to catch the same run. The ore is zinc-blende.

—Pat Ryan and associates have discovered a rich run of silicate ore northwest of Galena. The shaft entered the ore at 73 ft. Development has demonstrated the existence of a large area of mineralized ground. A horse-worm is now being used, but steam hoists and boilers are being installed. A walking beam pump is sufficient to handle the water. In the same vicinity, Ashen & Co. have developed a run of silicate at 75 ft. A drift has been made. Bowers, Butler and Hymel are working from 50 to 200 lb. are being removed. The larger pieces are ready for the market, but the finer ore is treated on a custom mill. A small amount of free-lead ore is found also. The Lizzie D. Co. at Peacock is planning for the erection of a 150-ton mill in the near future. The Company is operating in a shaft 135 ft. deep, the face being 11 ft. high. The ore is hauled up awaiting treatment. A St. Louis company, under the local management of Ed. Sparrrow, is developing a tract at Badger. A shaft is in ore at 180 ft. Extensive development and prospecting has been done and indications suggest a sheet-ore formation. What was supposed to be bedrock has been found to be full of ore.

—The Riverside mine at Peacock is to be revived after being shut-down of more than a year. This mine at the time of closing was driving under the channel of Spring river, having opened up an old underground water course. The company ceased operations, fearing that blowing would destroy the roof of the drift and cause the river to flood the rich Peacock district, as it is practically all connected by this old water channel. Operations are to be resumed, but new driving will be done in an opposite direction to develop the opposite channel of the Spring river. A 125-ton plant is on the ground. Repairs are being made at the Virginia mine in Baxter Springs to re-open that plant after a shut-down of more than a year. The Mason mill is also to be re-opened. When last worked
it carried a 37-ft. face of ore running 5%.—The Atton mill has been leased by J. W. Rice and operations started. This plant has not been operated for two years.—The Good Luck mill, recently completed, is still working on the dump pile. As high as a ton per hour has been made the past week. Underground work will be started the coming week, as the dump is nearly worked out. Both shafts will be opened. One shaft shows a fine run of galena.—The Heap-O’Urhien property is developing a 30-ft. face of rich galena and zinc-blende in a thorough manner. The company plans the early erection of a modern plant to handle the deposit.—The Joanna lease has been taken over by J. W. Creech, of Joplin, and the property is being re-opened. A large pile of block galena is in the bins and both galena and silicate are ready to be hoisted.

Galena, October 29.

MISSOURI.

LAWRENCE COUNTY.

(Special Correspondence).—General activity increases in the Aurora camp at the extreme eastern end of the district. Strikes have been made recently on the Speakerite, the Boston-Aurora, Cleveland-Aurora, and Big Bonanza tracts. A large part of the turn-ins comes from the shallow mines. About 16 new shafts are being sunk.—The United Zinc Co. has started the pumps at its No. 6 and 8 shafts and will commence work when the ground is drained. The mill on the property has been closed down for ten months, but weekly turn-ins have been made by the sub-leases on the shallow ground.—Practically all the properties in the Sarcoxie camp are active. A shaft is down 290 ft. on the J. W. Boyd land, west of town, and driving has been started at 160 ft. A concentrating plant will be erected. The ore in this camp occurs from 16 to 160 ft., the shallower runs being mainly silicate, while the deeper deposits are very rich zinc-blende. At a depth of 14 ft. a rich vein of silicate was discovered on the Henry Cule land west of town. The contract has been let for the erection of a mill on the Cameron lease on the Boyd land. The company has been engaged in developing the tract for the past three years. A large shaft is sunk and the ground thoroughly tested in every direction. The ore is high grade zinc-blende.

Aurora, October 29.

NEVADA.

EMERALDIA COUNTY.

The February Premier M. & L. Co. started work last week on its lease on the February claim of the Consolidated, at Goldfield. The head-frame was moved from the Jasper and a 40-hp. electric hoist has been put in. J. F. McCumber is in charge. A larger compressor was put in at the Baby Florence last week, the old one proving too small.—The Gold Bar Fraction Mining Co. has let a contract to J. M. Bench for 250 ft. of shaft work at $36.50 per foot, the contractor to furnish all material, tools, and labor. —The Goldfield Cl Mill Co. has contracted with L. K. Kornitz for 500 tons of ore from the Gold Bar mine.—The Wilson lease on the Grizzly Bear has been assigned to the Grizzly Bear Mining Co., which is composed of Goldfield men.—The C. O. D. Consolidated Co. has granted a new lease to the C. O. D. M. & L. Co., beginning November 1, when the present tenure expires. John Donnell & Co. has secured control of the company’s stock and will re-organize with a new board of directors and officers.—The statement of operations during September of the various properties of the Goldfield Consolidated Mines Co. shows a gross profit of $132,659, which includes losses of $17,938 and $1511 on the operations of the Goldfield Mohawk Mining Co. and the Jumbo Mining Co., respectively. The combination mill treated 2367 tons of an average value of $55.86 per ton. The following extractions were obtained in the different processes: 52.016% by amalgamation, 20.904% by concentration, 23.929% by cyanidation, or a total of 97.449%. The cost of mining 4594 tons of ore was $3.15 per ton; the cost of milling 2367 tons was $6.13 per ton. These figures include development and general expenses. The only other earnings of the Consolidated were royalties from its various leases.

HUMBOLDT COUNTY.

After a shut-down of six weeks, occasioned by a broken cam-shaft, the Kindergarten mill at Seven Troughs resumed operations last week. The mill is at present working on Kindergarten ore of the value of $90 per ton. After running through approximately 160 tons of this ore the mill will be turned over to the Wihuja people, who will also run 100 tons. The Wihuja ore, though conservatively estimated, will go $175 per ton. Following these two runs the Seven Troughs mine will take over the mill for a run of several hundred tons of Fairview rock.

NYE COUNTY.

A suit was filed in the District Court last week by the Daisy Mining Co., of Round Mountain, and J. J. McSorley, one of the directors, against F. W. Nixon and F. W. Stephenson, alleging that by an agreement in writing the said parties agreed to sell and convey to the plaintiff certain water rights and water of the Shoshone and Jefferson creeks for the sum of $25,000, and to deliver a good and sufficient deed to said water rights to the plaintiff, and that they have refused and neglected to do so, notwithstanding that the sum agreed upon has been paid.—Steady development and prospecting work is being carried on throughout the Midway property, and a great deal of new ground is being opened up. Several of the cross-cuts are in a very promising formation, and it would not be surprising to hear of the cutting of a new orebody any day. During the week the regular shipment of 100 tons of ore went out to the mill.—Corder & Berle started work on the Wall Street mine last week. They have a big body of ore that runs between $40 and $60. The Wall Street mine is in the South Bullfrog district, and Los Angeles capitalists are interested in it.—A carload of ore was shipped from the Tramp Consolidated mine last week to the Taylor & Brunton smelter at Murray, Utah. The car contained 22 tons of ore, taken from the David Brown, and of an average value of $100 per ton.—It is expected that the Campbell & Smith custom mill at Batty will be ready to operate within six weeks.—The mines of Tonopah produced during the week ending October 31 a total of 5108 tons of an estimated value of $129,575.
MINING AND SCIENTIFIC PRESS  November 7, 1908

WASHINGTON.

NORTHWEST.

Alleging gross mismanagement on the part of the present officials of the Selby Consolidated mine at Jumbo and stating that on account of this mismanagement many thousands of dollars are being lost, Fred Studtmuller, a heavy stockholder and secretary of the Company, has filed a complaint against the Selby Consolidated M. & M. Co., asking that a receiver be appointed by the court to take charge of the mine and work it according to the orders of the court.

NEW MEXICO.

GRANT COUNTY.

Sylva mine, a new camp, 12 miles south of Hackita and 25 miles north of the Mexican boundary, is attracting considerable attention because of the discovery of rich gold ore. The district is not a new one and mining of low-grade ore has been carried on in that locality for more than a century. It was at the exact location of the new camp that the dry placer boom failed last February. Some of the prospectors attracted by the latter remained in the hills and have found the rich ore which is the cause of the present excitement. The exact nature of the ore is the subject of considerable discussion among mining men and geologists, some maintaining that sylva mine is present and others that the white tin-silver mineral is tetradyline. However, none dispute the fact that free gold is present in quantities varying from $50 to $500 per ton. The proximity of the camp to railroads and smelters makes it particularly attractive, and it is claimed $15 ore could be handled at a profit.

OKANOGAN COUNTY.

Number One Mining Co., of Nighthawk, will install a 25-ton concentrating plant to handle its own ores. A. B. Lee, a director, announced at the close of an inspection, that the plant will be in operation next April. The property is owned by the Grand Ohio capitalists. Development work is being pushed on a drift on the vein, which gives a depth of 200 ft.

Mr. Lee says the vein is 35 ft. wide, with 9 ft. of concentrating galena and copper ore. The management of the Nighthawk mine, near Oroville, will increase the capacity of its new mill to 200 tons as soon as possible. The ore now handled is a soft quartz and easily crushed. The company expects to treat 100 tons per day until the alterations are made. A huge vein of high-grade silver ore has been opened on the mine, and there is enough ore in sight to supply the mill. Work on the Golden Zone, near the Nighthawk, has been resumed after a shut-down of several years. This mine is one of the oldest properties in that district and thousands of dollars have been expended in development work.

CANADA.

BRITISH COLUMBIA.

J. A. MacLeod and H. A. Shallenberger, of Spokane, have bought the Hastings group of ten claims, comprising 500 acres of ground at the junction of the Salmon and Pend d'Oreille rivers, 16 miles east of Wanata. This property has been known for years as the biggest deposit of hematite in southeastern British Columbia, but only recently has it been discovered that the iron was the capping of an immense lead-silver deposit. This hematite deposit is more than 4000 ft. long and 200 ft. wide. Open-cuts and short adits have shown up large bodies of lead and carbonate ore running from 40 to 60% lead, with some gold and silver. Along the course of the lode immense quantities of hematite, carrying on an average of 62% iron and from $2 to $5 gold are exposed. Ten men are doing development work.

—Announcement is made in Spokane that the option for $65,000 obtained on the Golden Zone mine, near Hedley, in behalf of the Daly estate, last summer, has been forsoaked. The option was secured by G. P. Jones, superintendent of the Nickel Plate mine at Hedley, but the general impression is that it was for the Dales, who own a controlling share in the Nickel Plate property. The mine is a gold property and has a 5-stamp mill.—Centre Star mine, of Roksinan, British Columbia, is now shipping more ore than ever before, due to the increased facilities afforded by the Trail smelter. Taking the Centre Star and the Snowbank orebody on the boundary, together, more than 1000 tons of copper ore is treated daily. In addition to this there are 2000 tons of lead and other ores being put through the furnaces every week.—Reports from Nelson are that the Queen Victoria mine of British Columbia is now on bond to Senator Clark, of Montana, the amount paid being $56,000. A compressor has been installed and the new wsex-wood is completed. Seventy-five men are employed, and it is stated that 500,000 tons of ore is blocked out.

MEXICO.

CHIHUAHUA.

(Special Correspondence).—The property of the Sahuyacan Mining Co., of Pittsburg, comprises 120 pertenencias in the Rayon district, 125 miles west of Mifaca, a station on the Chihuahua & Pacific railroad. It has been a steady producer for several years, though its production has been curtailed this year. The working shaft is 600 ft. deep and there are some adit levels from the surface. In all there are 10,000 ft. of development on a vein that strikes north-east-southwest between an undisturbed hanging wall and a shale foot-wall. The ore runs 25% to 30% in tons in gold and silver, 90% of the product being recovered on the amalgamating plates in the 20-stamp mill. Steam power is used for all purposes, though a water-power installation may be made next year for operating the mill. George E. Howard, manager for the Company, states that the Sahuyacan is being acquired by the Pennsylvania-Mexican Co., which is also expected to get control of the Santa Teresa, an adjoining property which has blocked-out ore valued at $750,000. By building an extension to the Sahuyacan tramway the ore from the Teresa may be deliv ered to the mill.

MIFACA, November 1.

SONORA.

(Special Correspondence).—The mine of the Lucky Tiger Combination Gold Mining Co., situated 30 miles east of Ysabel station on the Nacozari railroad, is under option to the Consolidated Mines Selection Co., of London, at $5,500, 900. The terms of sale, if the option be taken up, call for half cash on January 1, 1906, and the remainder one year thereafter. The preliminary report on the property was made by Frederick F. Sharpless, of New York, for the London company. At El Paso it is the impression that the sale will go through. The price named is at the rate of $100 per share for the stock of the Company. The mine is opened by adit levels and has 17,000 ft. of development work. A depth of 500 ft. on the principal vein has been attained by a half mile of adit, all but one of which is on the vein. There are two veins, but the one on which most of the development has been done is 4 to 6 ft. wide, having a dip of 65 to 75° to the west. The ore consists of sulphides of lead, iron, copper, and zinc, carrying gold and silver. It is stated that the shipping ore and concentrate produced at the 30-ton mill will average $600 oz. silver and 2½ oz. gold per ton. The vein strikes north-south through a chalybite country. The most of the stock of the Company is held in Kansas City, S. C. Boye being president.

NACOZARI, October 27.
Special Correspondence.

LONDON.

Definition of 'Mineral.'—Law suit Over China Clay.—Expert Opinions.

—A New Explosive.—Cornish Mining.

In Mr. Rich ard's book on 'Technical Writing' reference is made, among other things, to the confusion caused by the many different meanings of the word 'mineral.' A most interesting example of the conflicting ideas regard ing common terms is to be found in the recent lawsuit between a railway company and a china clay company, in which the whole dispute turned on the question as to what a 'mineral' is. This lawsuit was heard in the Court of Chancery, and in order to preserve my reputation of being up to date, I ought to have written something for your pages on the subject before now. I have to confess that this delay on my part has been due to my inability to find the real cause for the necessity for such a lawsuit. It lasted for a week or so. Eminent lawyers conducted the case, and the witnesses included names that are household words in the mining world. I have read the arguments and the evidence, also the Judge's decision. It was only when I discovered that the parties were talking at cross-purposes over the meaning of the word 'mineral' that I fathomed the case.

The lawsuit was brought by the Great Western Railway against the Cappalpa China Clay Co. and Lord Clifden, to prevent the continuance of excavations near and under the railway company's land. The spot where the workings are situated is in Cornwall, near St. Austell, in the neighborhood of the town of Max. This railway is a short branch line built specially for china clay traffic, and not used for public passenger transport. The railway company, or at least the company that was the predecessor in the ownership of the line, bought the land from Lord Clifden's father in 1881. The purchase was made according to the terms of the Railway Act of 1845. By this act the purchase of the railway company's land, and their workings had recently come within such clauses, as to give the company a stability. Accordingly the Cappalpa company gave notice to the railway company according to the Act of 1845, which provides for these cases, but the railway company ignored the notice and, instead, brought this action against the Cappalpa company and Lord Clifden, with the object of stopping the excavations in the vicinity of the railway. The railway company's argument was that china clay was not a mineral, and that therefore the Act of 1845 did not apply.

The evidence on the side of the railway company was given by Prof. Lapworth of Birmingham, Prof. Boyd Dawkins of Manchester, Dr. F. H. Hatch, and others. They gave interesting discourses on the origin and nature of china clay, and said it was not a 'mineral.' Their reasons for denying it the character of a mineral was that it was a heterogeneous mixture without definite composition, physical qualities, or crystalline form. They preferred to call it a weathered rock, or a rock debris, or a half-formed surface deposit not much different from a soil or sub-soil. They argued that recent microscopic examination has shown it to contain, besides hydrated silicate of alumina, a certain amount of silica, quartz, and unaltered feldspar, and in no case could they find the presence of the definite crystalline form of kaolinite. This evidence and these views and opinions are of course of great interest, but they helped rather to give the mineralogist's definition of a mineral than to help the parties in the lawsuit to an agreement.

For the defendants an equally brilliant array of witnesses was brought, including Prof. S. H. Cox of the Royal School of Mines, Prof. W. Gregory of Glasgow, Mr. Berndict Kitto, Mr. J. H. Collins, and others. These gentlemen showed that china clay had always been considered as a 'mineral' until the witnesses for the plaintiffs and introduced this latest refinement in mineralogy. They stated that the whole china clay industry of Cornwall, and the laws and regulations relating to it, have been formed on the supposition that it is a 'mineral.' The Judge upheld this contention and gave his decision against the railway company. He considered that the arbitrator in the latest phase of mineralogical science, and said that all he was called on to do was to give his judgment as to what is a 'mineral' within the meaning of the Act. He had no doubt whatever that an Act which referred to "coal, ironstone, slate, and other minerals," intended that china clay should be included. In fact, to his mind, a 'mineral' within the meaning of the Act was any substance found in depth that gave to the land a value on account of its surface value. The Act specifically mentions coal and slate, neither of which could be called a 'mineral' by the railway company's mineralogists. He also inferred that granite and other building stones are intended to be included among the 'minerals' of the Act.

It will thus be seen that to a mineralogist a 'mineral' is a substance possessing definite chemical properties and incapable of being separated into constituents. To a biologist a 'mineral' is any solid substance that does not belong to the animal or vegetable kingdom. An ordinary commercial man considers a 'mineral' to be anything in the earth below the soil that is worth digging out. To other people, a 'mineral' is a compound of chemical elements which is the subject of mining. It may be said that you have to pay lawyers' fees in getting a definition, it may appropriately be said that you "pay your money and take your choice."

A new explosive suitable for mining purposes is being introduced by influent people, called 'steelite,' named after the inventor, Mr. Everard Steele. So successful have the first results been that a company has been formed called Steelite Explosives Ltd., with a view of mining additional capital. Among the directors are Prof. W. Gatloway, well known as an authority on coal mining, and Mr. Max Muspratt, one of the famous family of chemical manufacturers. The special virtue of 'steelite' is that hygroscopic chemical, such as nitrate of ammonia and chlorate of potash, can be used. Hitherto such substances have been stored in drums or boxes, which have kept them dry, and by hitherto, have always been dry until they were put into use. According to Mr. Steele's invention, the nitrate of ammonia or similar substance is coated with a thin film of nitrated resin. This is effected by grinding the nitrate to fine powder and mixing it with from 10 to 15% of nitrated resin, and then subjecting the mixed powder in the form of a spray to the action of atomized alcohol or methylated spirit. The alcohol dissolves the nitrate, and causes it to adhere to and surround the particles of nitrate. The process is not conducted in one operation. It is preferable to add the nitrated resin in instalments and to spray several times with the spirit. The chemists and mining engineers who have examined the explosives produced by this process have reported favorably. The 'steelite' can be stored indefinitely without deterioration. It can be exploded either by a detonator, or it produces no fumes that are injurious to miners. The company will take over the experimental works in Lancashire and in Wales.

The troubles that come to Cornish mining are endless, and I have chronicled them in this column from time to time. The latest knock-down blow is the failure of Whael Jane. This old mine, near Tav, was acquired by the Messrs. Schiff 18 months ago, and a company called the Fairmont Consolidated was formed to re-open it and equip it with modern plant. Plenty of capital was forthcoming from influential quarters in the English and German metal trade, and the engineers were F. Dietesch and H. C. Jenkins. Large sums of money have been spent in erecting a
new plant. This plant was completed a month or so ago, and now we are suddenly informed that it will not work to specification. Most of the work on it has been discharged, and a meeting of creditors has been held. No doubt efforts will be made to provide more money, probably under new auspices and management. The reason alleged for the collapse is the failure of the mill buildings. There are four of them, each with an alleged capacity of one ton per hour. They are the invention of the eminent metallurgist, Emilio Ferrari, and they are made by Edgar Allan & Co., of Sheffield. I do not want to be unfair to the inventor or the maker. All new machines must have a trial, and no obloquy attaches to their first failure. What I want to point out is that mining engineers should not adopt new plant solely on the manufacturer's guarantee. This guarantee is no protection, for it only means that the manufacturer will have to make good the deficiency of the particular machine. It does not cover the cost of operating the mill and mill during the time the faulty machine is in work, or of the delay in providing a substitute. The company will require more money in addition to what will have to be spent on new crushing plant; for instance, no pumping has yet been done, and this will be absolutely necessary before any development can be carried out. The mine has been worked for generations above the adit, and it can hardly be expected that much can be found without extensive prospecting at lower levels.

JOHANNESBURG, TRANSVAAL.

Amalgamations.—The East Rand.—Mineral Output.—Diamond Mines.

—Bushveld Tin.—Trades School.—Status of Engineers.

Barney Baranto, the famous speculator of the Kimberley and Johannesburg early days, was once asked chaffingly by an acquaintance how he would find further scope for his speculations when he had consolidated all the mines into one concern and no further amalgamations were possible. He is said to have replied: "Well, my friend, I should proceed to split them up again." It seems that we are rapidly arriving at the stage when amalgamations will no longer be practicable, but the process of subdivision will only be evident upon the final exhaustion of the units of combination. The completed amalgamations of the Norval mines, of the Village Main Reef and Wemmer, of the Village Deep and Turf mines of the East Rand Proprietary subsidiaries, and of the Sinmar Deep properties, only mark the beginning of the policy that is being followed so energetically from end to end. The limiting factor is the division of Rand interests into different financial controls, not always disposed to combine forces. During the past week these schemes of amalgamation for mines in the East Rand have been carried. First, under Eckstein control, the consolidation of the properties of the Modderfontein Extension and Transvaal Lands & Mines Proprietary Syndicate into a new company with a nominal capital of £700,000. A sum of £14,900 is provided for immediate working capital, and as the property (of 13,300 acres) is an outcrop one, production should be commenced in 1910. The other amalgamations, virtually completed, are those of the Chimes West & Benoni, and of the Van Ryn Deep and Kleinfontein Deep. All these properties have come into favor by the remarkable developments occurring in the Brakpan mines to the deep. Other consolidations are on foot, notably in the case of the South Rand and Caw Reef, and in the region of the East Rand Extension.

The Government statistics for August show the mineral output of £5,555,497 for the month to have been made up as follows:

<table>
<thead>
<tr>
<th>Mineral</th>
<th>Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>Gold (Raud)</td>
<td>£2,397,256</td>
</tr>
<tr>
<td>Gold (outside)</td>
<td>£6,259,310</td>
</tr>
<tr>
<td>Coal</td>
<td>£1,101,101</td>
</tr>
<tr>
<td>Other products</td>
<td>£2,504,034</td>
</tr>
<tr>
<td><strong>Total</strong></td>
<td><strong>£5,555,497</strong></td>
</tr>
</tbody>
</table>

The minerals not specified above include copper, tin, and galena. Labor figures are up at a high level, and for the Rand alone indicate the following totals: Whites, 17,924; colored laborers, 141,860; and Chinese, 17,270. Total, 177,090. The Transvaal diamond mines employ 942 men, white and colored; and the coal mines, 9,882.

The Voorspoold diamond mine in the Kroonstad district of the Orange River colony, one of the biggest and most recently discovered pipes in South Africa, is profiting by the considerable improvement in the diamond market, and has commenced washing with a new plant. The September returns show a good grade, namely, 21.95 carats per 100 loads washed.

The Premier diamond mine, of whose mining operations little has been heard for some months, owing to the policy of secrecy prompted by trade depression, appears to be making preparations rapidly for a greatly increased production. A new plant capable of treating no less than 40,000 loads (16 cu. ft.) per day will be completed about the middle of next year. With working costs already in the neighborhood of £3. 9d. per load, the calculated profits are enormous, but in spite of the directors' confidence in their strength, it is clearly impossible to predict the effect of this vast scale of operation upon the world's market and what the attitude of De Beers will be in regard to such a competitive factor.

It is not a little surprising, in view of the ignominious collapse of the mining in the Bushveld two years ago, to note a return to these former sites of lamentable failure. The lodes of the Bushveld Tin Mines, Ltd., are being reopened and discoveries have been made, inspiring those in control to declare that a faulty policy was adopted in the past and the system of lode occurrence misunderstood. Similarly, the property of the S. A. Lands & Exploration Co., in the Bushveld, is being re-investigated with promising results.

A question that is gaining rapidly in importance and receiving renewed attention is that of the training of artisans and engineers in South Africa. While we must admit the advisability of obtaining the best trained technical men regardless of nationality, there is urgent need for making the most of the raw material available in the country. The last meeting of the Transvaal Institute of Mechanical Engineers was devoted to the reading of a paper on this subject by the president, Professor Orr. The Professor referred to a proposal of the Government to establish a Trades School, and urged strongly that such should not be made the means of imparting closely specialized instruction in the chosen trade. He wishes to see lads given a better general education therein, supplemented by general technical instruction in one or more branches of mechanical knowledge. There are other mines or other institutions. In this contest he gained entire support. As he pointed out, South African mines provide a most admirable place for a fitter or engineer to serve an apprenticeship, owing to the great variety of work. An ex-student of Cornell, and for some time apprenticed to the Westinghouse firm in the States, supported the view as to the desirability of the miners turning out good all-round men, without the danger commonly bemoaned by the engineering aspirant of being put too exclusively to narrow departmental work. Following the instruction of the Trades School, there will always be the opportunity of extending theoretical and practical studies at the Transvaal University College, which caters admirably for students in the various branches of practical knowledge. Following upon a discussion of these points, the old vexed question was raised as to the possibility of giving a status to members of the engineering profession, a question which has indeed been a troublesome one in many countries. However, already in this colony land-surveying forms a closed profession. Mine-managers, resident engineers, mine-surveyors, mine-capitaines, and, of course, engine-drivers have to pass fairly stiff examinations for Government certificates; still, nothing prevents the humbug from practising as a consulting engineer and obtain-
lugging business from the public on the strength of his own claims to qualification.

The problem presents difficulties of universal recognition. Indeed, even now and with sound cause, there is a strong opinion among men of the highest position and qualifications that the Government should modify its regulations as to the certificating of managers and foremen of smelter, for the advancement, the conduct of examination and its object. The subjects prescribed are: mine surveying, mining laws and regulations, mechanics, chemistry applied to Rand metallurgical practice, and optional geology, with mineralogy. Clearly, the object of the Government is to have some hold over the men responsible for the safety of the mines and to learn if those placed in control appear to be technically qualified. Assuming that dangerously incompetent men might otherwise be pitchforked into high positions (a supposition not tenable in these days of stern competition and high efficiency, as regards the Rand), such an investigation is clearly desirable. But the trouble is that it does not always serve this end and there are several notable cases of men with long practical experience, proved capable and trustworthy by the test of actual emergencies in working practice, and selected by the great mining firms as the best men available to fill positions of high responsibility, who have been 'plucked' repeatedly under the test of the Government examinations. At times, no doubt, such questioning has merely revealed a lack of knowledge of serious magnitude, but it is not right that reliable men capable of unimpeachable mine to management should be trip-trapped by the trickeries of assay operations, of the...  

**BUTTE, MONTANA.**

**Copper Production in October.—Mr. Ryan’s Forecast.**

The estimated copper production of the Butte mines during October was 28,564,410 lb., against 29,055,000 in September and 28,121,000 in August. The Boston & Montana, Anaconda, Butte Coalition, Butte & Boston, and Washoe companies show increases, and North Butte, Original, Trenton, Parros, and others show small decreases. The various companies contributed as follows:

</tbody>
</table>

The average yield of copper per ton of ore mined by the various companies is: Boston & Montana, 77; Anaconda, 53; Butte & Boston, 62; Washoe, 69; Parrot, 58; Trenton, 56; North Butte, 92; Butte Coalition, 80; Original, 82; Pittsburg & Montana, 89 pounds.

John D. Ryan, managing director of the Amalgamated, who is spending a short time in Butte, speaks hopefully of the future, but says better prices for the metal can not be expected until business conditions throughout the country get better. "The metal market has shown a marked improvement during the last week, and large sales of copper have been made at slightly advanced prices," he said. "The price, of course, is still quite low, and while the demand seems very good at present, general business of the country has not gotten back to anything like a normal level, and the quotations on copper probably will not show any marked advances until there is a greater recovery in all lines of trade. One very encouraging feature in the recent large sales of copper is the fact that most of the metal has been sold for domestic use. The mines are in full operation and there is no accumulation of copper. Incidentally, there is no indication that payrolls in Montana will not continue to be large and regular during the winter. In this respect I think the mining and smelting communities of Montana, in common with the lumber and agricultural centers, ought to see a prosperous year. Arrangements were made since I have been East to push the development of the water-power at Great Falls, and as many men will be given employment there during the winter as possible."

The treasurer of the North Butte Extension Copper Mining Co. has made a report to the stockholders, covering the expenditures of the Company up to the time when he was elected, on June 27. It says that charges were made for the property $251,215, and for equipment and development $724,531. In addition, there is a miscellaneous account which brings the total cash expenditure up to $425,426. This amount, according to the treasurer, A. M. Andrews, represents the value of the property aside from the enhanced value resulting from the expenditures, and the opinion of those competent to judge the value of the property is that it is far in excess of the amount of money actually expended. A report from New York states that an extension of option on the Míchiganer and Tchirb Sphax has been obtained by the Company.

**SALT LAKE, UTAH.**

**Utah Copper Railroad.—The Garfield Plants.—Tloche News.—Utah Can. Smelter.**

It has been estimated that it will cost the Utah Copper Co. $1,000,000 to build its proposed railroad from Bingham to Garfield and equip it for business. Whether the line is to be built out of the general earnings of the Company or whether bonds are to be issued has not been fully determined; but it has been figured that the road ought to pay for itself within two years. As I have previously stated, the Utah Copper Co. would never have engaged in the railroad business had it not been forced to it by the Denver & Rio Grande railroad, upon which all Bingham producers have depended in the past to transport the products of their mines to mill or smelter. The latter has rendered such poor service that many have had just cause to complain, and notwithstanding that the Bingham branch is reputed to be the best paying portion of the Rio Grande system, it seems strange to a good many that the management has not been more careful to look after the interests of its patrons instead of inviting competition. Some idea of the earning capacity of the new road may be gained from the fact that the present mill of the Utah Copper Co., at Garfield, calls for 6000 tons of ore daily—and the management contemplates increasing this to 10,000 tons next year. The Boston Consolidated mill at the same place, when all the equipment is installed, will require 3000 tons per day; while the Utah Consolidated is shipping to the Garfield copper smelter at the present time 800 tons per day, upon which a freight charge of 40c. per ton is exacted by the railroad through the operation of an old contract. The Utah Copper and Boston Consolidated ore is hauled several miles farther, and the expense to these mines does not exceed 25c. per ton. But supposing the average from the three properties mentioned, to say nothing of the others in the Bingham district, was 25c. per ton, the earnings from ore freightage would run up to $2500 per day. With the road built, the Utah Copper Co. will reach out for traffic wherever it can get it.

Representatives of a large smelting company have been making overtures to the officers of the Prince Consolidated Mining Co., operating in the Tloche district, but which has its headquarters in Salt Lake. The mine contains a large deposit of iron ore of a character that is desirable. Engineers claim that 2,000,000 tons of this material, which also contains gold, silver, and lead, has been blocked out; while in separate veins a large quantity of high-grade...
silver-lead ore has been developed. In addition to this, the Company owns the Bullionville tailing dump, containing approximately 171,000 tons, left from mills operated in the early days of the Pioche district. The stock was recently listed on the Salt Lake Exchange, and the application for admission to the New York Stock Exchange, if granted, will mean that the Company has cash assets of $12,500 and is the possessor of 1300 acres of mineral and other lands near Pioche.

The sales on the Salt Lake Stock & Mining Exchange during the 10 months ending October 31, aggregated more than $18,000,000, which exceeds by about $1,000,000 the total sales of last year. The management has had plans drawn for a new exchange building, which is to be erected in the new financial centre of Salt Lake at a cost of about $100,000. The land upon which the structure is to stand was donated by Samuel Newhouse.

Although the operating department has released nothing confirmatory as yet, the impression prevails that instructions have been received to prepare for the construction of the proposed Utah Consolidated smelter in Tooele county. Engineers were on the ground last week. Urban H. Broughton, the president of the Company, is much in earnest about this new smelter, notwithstanding the opposition from the directors favorable to the Guggenheim's smelter trust. Mr. Broughton is quoted as having said that the Utah Consolidated mine contains a much larger tonnage of ore than it did a year ago; that its condition justifies the erection of a smelter, and that unless the American Smelting management agrees to a better rate than has yet been mentioned, the construction plans will be carried out; which means the expenditure of between $2,000,000 and $3,000,000 for the purpose stated. The Company has already expended $150,000 in the purchase of land, water rights, and smoke easements.

MEXICO.

Gabriel Latour and the Monterrey Steel Works. — Zinc Properties. —

News from Oaxaca.—Good Work at El Oro.

Rumors has it that Gabriel Latour, who is so heavily interested in the coal and iron fields of Alabama, is on his way to Mexico, and will examine into the affairs of the Monterrey Iron & Steel Co., with the idea perhaps of taking it over, or at least obtaining control of it, and possibly merging it with his interests in the States, which company, the Oceola Iron & Coal Co., and the Alabama Consolidated Coal Co. It certainly is to be hoped for the good of Monterrey and its steel works that the rumor may be founded on fact, for ever since the start, the Monterrey company has needed some one who thoroughly understood the business. In the zinc circles of Monterrey also there seems to be a light awakening of interest; the more important movements in which being the purchase by the Empire Zinc Co. of the Pefiasaro mine and dump, situated near the Fierro station in the State of Coahuila; and the acquiring of control by Pablo de los Santos, of Sabanas Hidalgo, in the Cruz del Aire mine near Sabanas Hidalgo, which from a little lead prospect four years ago has developed into such an excellent lead and zinc producer that De los Santos paid $174,000 for 420 of the total 1200 shares. De los Santos is also heavily interested in a number of other lead and zinc properties in this district.

From many other parts of Mexico come even more favorable reports, which may or may not be in part the result of the elimination of the famous Article 144 of the new mining law. In Oaxaca, to which the larger smelters have paid but little attention, it having been looked upon as territory for the Texutlan Copper Co. and independent ore-buyers, both the Santa Lucia and the Oaxaca Monterrey plant of the A. S. & R. Co. have had representatives in the field during the last month and it would appear as though they were endeavoring to contract all available ore before the Oaxaca Smelting & Refining Co. begins the purchasing of ore for its Oaxaca smelter, which H. M. Holbrook is quoted as saying will blow in as soon as possible after January 1, 1899. The Santa Catarina, controlled by

Boston capital and in charge of Arthur Buttner, has 10 additional stamps engaged in experimenting on the further treatment of the ore and without much doubt a large scale plant will be added shortly. The Oceoro Mining Co.'s property in the Nochistlan district orders have been given and construction work started for a 10-stamp mill. The Navidad Co. is erecting its new cyanide mill under the superintendence of W. B. Washington. And the Santa Sofia Mining & Milling Co., also of Oaxaca, expects to begin the erection of its 100-ton mill about the first of the year.

In the San José district work is well under the ground. The King. English engineers are examining the Nativid, and examinations are also being made on the Zapote. In the Ejutla district a deal is on for the San Francisco and H. B. Hall has taken an option on the Hortencillo. In Tlaloculco, the Marissa & Anexas Co. is preparing to resume operations, and an 8 kilometer tramway has been ordered for the Montes Exploration Co. of Tumantli. At the Guadalajara plant near the headwaters of the Citar River, in the Ejutla district, which was bought from Meets, Foss and Houston early in the year by Otto Mr. Hall (of San Antonio, Texas) and H. Greisdeck (of St. Louis, Mo.), a good grade of silver-bearing copper ore (30 oz. silver and 8 to 10% copper) has been cut on the 300-ft. level.

In the El Oro district of the State of Mexico, the four principal producers, the De las Animas, El Oro, and the Mexico, show a total production of over $9,000,000, with an expenditure slightly in excess of $5,000,000, so that there was left a profit of $4,000,100, their rank as producers being in the order named. The Mexican mines of El Oro show for a twelvemonth a production of 65,000 tons, with a profit of $325,957, the total expenses being $6.33 per ton produced, and the company reports as blocked 205,210 tons running 1/2 oz. of gold and 61 oz. of silver. The Somora has cut a 4 ft. vein assaying $40 per ton 150 ft. west of its Patricio shaft; and a rich gold and silver strike is also reported from Los Ocotos Mining & Milling Co., of Tlatujahua. The Victoria y Anexas continues cross-cutting in search of the several veins crossing the property. In Zacualpan, Mexico, the La Cuchara Co. is opening up a large body of lead and zinc ore and a large concentrating plant has been ordered.

KALGOORLIE, WESTERN AUSTRALIA.

Chaffers Stock-Boom. — Unique Head-Frame. — Cassel Process at Oroya-Brownhill. — New Agitator and Slime-Filter at Associated Mine.—August Production.

There has been rather a boom in Chaffers stock during the month, due to tributors striking rich ore near the surface, and having crushed a rather high tonnage. This mine is on the south end of the Horsehoe, and, of course, has great possibilities. Spec. rose to a high price, and there is no doubt that the Fox is about perfectly covered but speculators do not trouble to look into that side of the question.

At Edwards' shaft, on the Great Boulder, the new headframe will be finished before this is in print. The legs are built of sections of steel piping, about 10 in. diam., and braced together with I beams, the whole standing on massive concrete gallery. The shaft on the Boulder are being built in, while the foundations for the hoist itself are being laid. When finished, this will be a powerful hoisting station.

After several months' trial of the Cassel process on its residue heap, the Oroya-Brownhill Co. has bought a plant near by, will enlarge it, and start treating 15,000 tons or more monthly. It is perhaps just as well that a start is
to be made on this enormous pile of stuff, as the boom distributor on top is now becoming a trifle unhandy to handle. The new Edwards’ duplex roaster at the Associated is almost finished. It is to be driven by a 15-hp. motor. This company generates its own power for lighting, various motors, and an electric hoist at Tietley’s shaft, on the lignan system, so well known in Germany. The duplex furnaces behind the shoulders should also soon be at work, while Moss’ Gold Recovery works are about to erect one of the same type.

For some time past the Associated has been experimenting with the A. T. agitator on its roasted ore, as it comes ground to slime from the pans and settlers. The rats here are of steel, about 16 by 6 ft., and the A. T. machine is driven at 60 rev. per min., taking 10 to 12 hp. Previously, the agitation of the slime by the ordinary vertical spindle with long arms attached took 20 hr. Now the A. T. machine does the work in about 3 hr., with a slightly better extraction, especially so if the roost has been at all poor. The ordinary type of agitator takes about 3 hr. The Associated has three A. T. machines at work, is installing two more, and is hoping to put all the old machines out of commission. A new slime-sifter agitator machine has also been evolved at this mine by one of the mill Foremen. It consists of a wide belt and cloth, on which the agitated pulp is run; the belt is then squeezed between rollers, and the solution runs through the filter cloth and the holes punched in the belt. The model works well enough, but the squeezing of the belt will tend to crack it in time. A working machine is now being constructed. It is thought that two or three machines in series should wash the pulp thoroughly, the work being continuous. The August outputs from the principal mines were as follows:

*Half of this profit is from the re-treatment of old residue.*

**CHAFEY, NEVADA.**

**A New Camp.—Dun Glen and Sierra.**—**Early Mining.**—**Story of Discovery.**—**Ore Shipments.**—**Geologic Conditions.**

During the past summer the old mining camp of Dun Glen, in Humboldt county, Nevada, has experienced a notable revival, and, under the new name Chafey, has attracted no little attention among the mining men of that State. This new-old camp is situated on the west slope of the East range of mountains, and lies mainly within Township 36 North, Range 26 East. From Winnemucca, the county seat of Humboldt county, it is distant 20 miles in a southwesterly direction, and from Mill City 10 miles south-easterly, both being stations on the Southern Pacific road. From these towns stages and automobiles run to and from Chafey.

Chafey is the usual aggregation of a few frame buildings and many tents. All lines of business are plentifully represented. Its proximity to a railroad has kept living expenses down to reasonable figures from the start. Meals cost from 25 to 50 cents, beds from 50 cents to $1. Numerous small springs furnish good water, but the supply is quite limited. Wood, such as juniper and sagebrush, covers the near-by hills in fair quantity. The population is close to 500, of whom not a few are unable to find work. The Tonopah scale of $4 per day has been adopted, but it would be futile for miners to go there seeking employment. In fact, until this has been another year for development, those now present are all that could properly be employed in the legitimate industries of the place. The first gold discoveries were made more than 40 years ago, when prospectors from Unioville, in the Humboldt range, crossed the valley to the east and in the East range discovered the mines that called into existence the camp of Dun Glen. These pioneers organized a district, called by them Sierra, and this name still endures. At this time Unioville was the most important town in central Nevada. The principal ore-reduction plant of that region was operated there; Raymond, of Raymond & Ely fame, was driving into the bonanzas of the Arizona mine, and the mining and financial activities of Humboldt county centred there. Mark Twain, as yet unaware of the quickening of his own genius, was an obscure resident of the place, and the gray-beard survivors of those days tell many yarns of him, of which Mark is not always the hero. The first ore brought to Unioville from the Sierra district prospects was the typical surface ore of most gold veins, a rusty, cellular, disintegrating quartz, with much visible gold. As this ore was found in many places over a considerable area, and throughout a series of several related veins, a stampede occurred upon the facts becoming known, and the camp of Dun Glen came into being. While its growth was neither rapid nor great, Dun Glen eventually grew to be a settlement of some few hundreds, and ranked next to Unioville in importance, at one time being a garrisoned military post, with a company of regulars. As the mines developed and increased in number, mills were built, and over half a million in gold was obtained from the mines of Monroe Hill, from the Auburn, the Auld Lang Syne, and other properties. Later, Dun Glen repeated the history of old mining camps, ancient or modern. As depth was attained both the character and value of the ore changed. The oxidized ore above the adit-levels was stopped and sulphides in quantity were found. Pyrite, chalcopyrite, arsenopyrite, galena, and sphalerite
mining the millenium, and vaniers were added to the equipment, but decreased extraction and increased costs proved a heavy handicap. Finally, the Monroe Hill vein was found to be faulted, and was not recovered. The Auld Lang Syne stope in a ground above the lower adit and then gave up the fight rather than sink below water-level, not withstanding the fact that the vein was still regular and undiminished in size, carrying gold associated with sulphides. The operation of the smaller properties of the district had previously ceased, and with the closing of the Auld Lang Syne, lode mining in Sierra district came to an end. It is true that small branches of ore were occasionally taken from the veins of Monroe Hill and recovered by the Cornish miner of the name of Hendra, but this dautsul work was not mining. Hendra had come into possession of the Monroe Hill and other mines, and one of the mills, and until his death, a few years ago, made a comfortable living in this manner.

During the year 1906 Hendra's widow and his daughter, owners of the property, gave long-time options upon the Heit hill prospect to Henry W. Kent, of Milwaukee, $10,000 being the purchase price. Kent organized the American Finance Co. and sold stock. As a stock salesman he was probably a success, but as a mine manager he distinguished himself simply by the facility with which he was able to fritter away other people's money, and therefore accomplished little in the way of development. However, in the little work done by Kent, during the winter of 1906 we find the initial cause of which the camp of Chafey is an effect. Into a self-covered hillside, devoid of quartz outcrop, or other indication, hundreds of feet away from the nearest mine-working of early days, Kent drove a cross-cut to intercept the lode. Within 2 ft. the vein was reached, and a drift was soon in quartz that sampled nearly $100 across 4 ft.; and there the drift stopped, for Kent would not permit a cross-cut point, and did not actually a cross-cut at any other. Kent's option expired by limitation in the spring of the present year, whereupon a new bond was at once obtained by Charles Harlowe, at the advanced price of $50,000. Harlowe had invested several thousand dollars in the Kent enterprise, all of which would be a total loss unless he could find a purchaser for the property.

Kent and Harlowe made the acquaintance of E. S. Chafey, Chafey is a successful young miner from Kansas. He first came into the limelight in Nevada through his having made a modest fortune by the sale of his interest in the Transvaal claim in the Bullfrog district, a so-called gold mine that does not produce gold. Later, he is said to have made another good sale at Greenwater. After Chafey saw the Hendra property and sampled the ore Kent had exposed, he was not satisfied. The mill is at hand and the small vein, was, was a real opportunity, and he thereupon undertook to raise the money necessary to handle Harlowe's option. Securing the financial assistance of a San Francisco friend, Chafey began operations in a small way, but with shipping ore to start on and only 10 miles to railroad, it was not a difficult matter to make the property pay its way. The first shipments are said to have been sent by wagon, but since then from 1,200 to 1,500 tons have been shipped, but there is no way of learning the value of this ore, since the management has refrained from giving authentic figures. Camp gossip and the statements of the local press to the effect that the total has averaged in excess of $100 per ton, net, need not be given serious consideration. That the shipments have been extremely profitable is not to be doubted, for the reason that运费 charged on tonnage amounts to about $1.50 per ton, the full payment of the purchase price of the property from the proceeds of ore shipped. In addition to ore sent to smelters and smelters, an equal tonnage has been worked in camp at the old Hendra mill. This ore is said to average $20 per ton, gold. Silver and lead are contained in the ore, but in too small amount to be of economic importance, even in the shipper's mills. The ore is a grayish-black and contains a matrix of three light stamps and a 5-ft. Huntington. Under favorable conditions the output is 30 tons per day, but a limited water-supply and intermittent coal-receipts often lessen the tonnage treated. A two-stamp, gasoline-driven mill has lately been erected by other parties, but its small capacity eliminates it from consideration as a factor in treating the ores of the camp.

Sierra district, as organized by the pioneers, is a large one. I did not cover it fully, nor do I know its exact boundaries, hence can do no more than generalize with regard to the local geologic conditions. In such portions as came under my notice—particularly those parts wherein the mines are situated—the general condition was that of extensive areas of the older sedimentaries (limestone and slate), and occasionally impure quartzite thinly interbedded with the slate), penetrated by a broad belt of intrusive rock. It is my belief that by far the greater portion of this belt is andesite, but I do not feel satisfied to attempt to pass upon this question of identity from mere field inspection. Possibly a determination would place this rock with the rhyolites, and in some parts of the eruptive area rhyolite is unmistakably in evidence. Wherever observed, the andesite has been much altered and has received abundant additions of silica. In consequence, it has resisted the weathering attacks of the elements and is characterized by rugged outcrops that stand out in bold relief. Having a width of fully half a mile by not less than four miles in length, and crossing the East range diagonally from valley to valley with a strike nearly north, this andesite belt has much the appearance of a huge plateau. In several areas near the veins, a schistose structure was observed, but it does not warrant the misuse of 'schist,' as the rock is locally called. Near its western limit several narrow dikes occur, intrusive within the andesite. Their course is nearly north, their width usually under six feet. The mines of Monroe Hill are found at or near the contacts. Of the contact veins observed, basalt was in all cases the hanging wall. The other veins are wholly within the andesite, and the same minerals are common to both classes of veins. A mile farther north, on the Auld Lang Syne property, the dikes appear to have converged, since but one is visible and that one having a width of 30 ft. Here only one well defined vein is found; course, north; dip, east, at 76°; width, 4 to 7 ft. Basalt forms the hanging wall, and andesite the foot. The hanging wall shows no alteration other than that due to weathering, but the foot-wall gives evidence of excessive chemical action. As much as 69 ft. in width, adjacent to the vein, has been altered by the same silica-bearing solutions that formed the lode proper, and where quartz-replacement of the porphyry has not been completed the porphyry has been so highly silicified as to destroy all original crystallization. Gold is contained in the more quartzose portions, but not sufficient to make of the mass a profitable ore. Many small specimens with the vein will be able to develop minerals were observed in any veins apart from the eruptive rocks. The limestone to the west and northwest will warrant close prospecting.

There is reason to believe that large bodies of low-grade gold-bearing sulphide ore will be found at depth throughout Sierra district, and the future prosperity of Chafey is certain if the old Hendra mill is developed and by such method as to show a profit on millstone running $10 per ton. Good management can accomplish this result, but any effort to establish the camp upon a stock-board foundation will be certain to bring failure, and naught but failure will follow, even with the best of intentions, unless men competent to apply the cost-reducing methods of modern mining are placed at the helm. High-grade ore will be found, but will not be able to develop profitable mines—and a mining camp untainted by those methods of illegitimate mining for which Nevada has become notorious.
Concentrates.

Most of these are in reply to questions received by mail, our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Amalgam loss by abrasion in treating a gold ore in an arrastre is undoubtedly due to keeping the amalgam too hard. The use of more mercury should remove the difficulty. The temperature of the water has no appreciable effect in softening or hardening amalgam except when steam or frost is involved.

Machinery paste said to possess superior qualities as a protector from oxidation is made by melting camphor in hard, in the proportion of 1 to 16 by weight. The mixture may be stiffened by the addition of ground graphite. The metallic surface must be thoroughly cleansed before applying the paste.

Blue-prints which have been over-exposed may be strengthened by applying a dilute solution of hydrogen peroxide. A print of deep blue color and clear lines will result. A solution containing 1 c.e. of peroxide to 50 c.e. of water is of proper strength. Some operators purposely over-expose and then tone up the prints with the peroxide.

Stockholders of record in a mining company organized under the laws of Arizona have no right to demand a statement from the company’s officers as to the affairs of the corporation, but they do possess the right of personally inspecting the company’s books. Their right to inspect the mines and works of the company will be governed by the laws of the State or country in which the properties are situated.

Annual labor performed upon one claim of a group only, in order to apply within the intent of the law as at present determined, requires that the claims must be contiguous, but not necessarily located upon a single lode or vein, and that the group of claims be held in common ownership, and further, that the work done upon the one claim tend to develop the vein or the entire system of veins covered by the group.

Gilsonite, more properly called uintaite, is mined by open-cut methods, being easily broken by the pick. It can not be blasted. We know of no application of mechanical excavators to this work, but we see no reason why some adaptation of the endless chain of buckets, after the ‘trench digger’ type, might not be advantageously employed. Most of the gilsonite fissures in Utah stand nearly vertical, thus favoring mechanical methods of excavation.

Cylinder oil in air-compressors undergoes partial combustion to carbon monoxide, owing to the high temperature produced in the cylinder, which ranges from 350 to 450° F. This gas, if produced in large quantities, so as to become mixed in the proportion of about 1 part of carbon monoxide to 2½ parts of air, is highly explosive. The gas is also poisonous, and the atmosphere in narrow working-places where air-drills are used, is sometimes rendered injurious from this cause. The remedy is to use a high-grade cylinder oil which is non-volatile and resistant to combustion at the temperature of the compressor cylinder.

Simpson’s one-third rule as stated in our issue of September 12 was in error, and should have read as follows: Divide the base line into an even number of equal parts and erect ordinates at the points of division; then add together the first and last ordinates, twice the sum of all the other odd ordinates, and four times the sum of all the even ordinates; multiply the sum by one-third of the common distance between ordinates. This rule gives the area of an irregular tract, if the position of the base line is properly selected, or it may be advisable to inscribe a triangle or series of triangles in the area and use their sides as base lines.

An arrastre clean-up is made by grinding down the last charge, with excess of feed-water, until the ‘drag’ is running on the bare pavement. The pavement is then taken up, each block being washed into a tub, and inspected for adhering amalgam. The remaining pulp is removed, and the ‘puddle-bottom’ scraped. This pulp is pumped down carefully to black sand and amalgam. The pannings are rubbed down with fresh mercury, the black sand floated off, and the dilute amalgam squeezed in canvas or chamois skin in the usual way. The ‘puddle-bottom’ should be carefully inspected, and repaired with fresh, well kneaded clay, to prevent escape of mercury and amalgam, before the pavement is replaced.

Infusorial earth is used chiefly as a polish-powder. It is of small commercial value on account of being restricted to local markets, where saving in freight will enable it to compete with the ‘volcanic dust’ from Nebraska. Immense beds of volcanic dust are worked on a large scale in that State, giving the operators a practical monopoly of the business. An infusorial earth of superior purity, and containing no admixture of clay, might find a market as a ‘dope’ for dynamite. On account of its micro-cellular structure it is the ideal absorbent for nitroglycerin. It is used abroad for that purpose, but no suitable deposits have so far become known in America.

Sea-waterproof cement, bearing the name ‘Aegir,’ is a product of a cement works at Hennoor, Germany, which it is claimed can be used with economy and efficiency for works constructed in sea-water, tunnels, and other places, where ordinary Portland cement will deteriorate. The raw materials used in its manufacture are: chalk containing 99.1/₂ to 100% of pure carbonate of lime; roasted quartz, very finely ground; and finely ground ferrie oxide. The ferrie oxide is obtained partly from bog-iron ore and from other purer iron ores. After the quartz and ferrie oxide have been finely ground, all the three materials are worked together into a moist paste. After having been dried the mixture is burned to clinker in the ordinary way. In other words, it is a cement in which iron oxide replaces the alumina.
**Discussion.**

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

**Decline and Revival of Comstock Mining.**

The Editor:

Sir—I have read the articles by Mr. Whitman Symmes with much interest. My own knowledge of local conditions prompts me to offer the following comment:

The work of the Comstock Pumping Association, formed in 1898 to unwater the Comstock lode at Virginia City, Nevada, is, after years of trying labor, beginning to be rewarded with results in the north-end mines. During the past few years an extensive body of ore has been mined on the Ophir between the 1800 and 2200-ft. levels. Within the past month ore in the Con-Virginia has been found on the 2150-ft. level lying between drifts previously run and the foot-wall of the lode; and in the Mexican, ore has been found by driving north from the 2200-ft. level of the Ophir. These mines adjoin each other, and were fairly well prospected 25 years ago on the levels where ore is now being found. The policy of the management at that period was to abandon the upper levels and to scatter development work between the 2500 and 3100-ft. levels; this has proved a mistake. It may take another 25 years of prospecting to prove or disprove the existence of ore in paying quantity, and to mine what is known to exist above 3250 ft., the vertical depth of the Combination shaft. To understand the reason, the following observations are made: The Comstock lode is from 100 to 250 ft. wide for the length of the main stem (without the branches), that is, for a distance of about 11,000 ft. Of the 20 principal companies that have operated on the main stem, all but two or three have had bonanza orebodies within their respective boundaries at some stage of their development. Some have had both a shallow (down to 500 ft.) and a deep (below 1500 ft.) bonanza. For the present, only the north-end properties, that is, those lying north of the Best & Belcher, are in a position to profit by the unwatering of the lode as far as it has gone; it will take several years for the remaining properties to be similarly benefited. The great extent of the lode, combined with the inability of the non-producing mines to collect assessments for work on a large scale, the lack of concerted action among the property owners, and the physical conditions under which work must be performed are some of the contributing causes why it will take many years thoroughly to explore the ground.

The late discovery of ore at the point where active prospecting was resumed when the water reeded draws attention once more to the most remarkable body of ore taken from the lode, namely, the bonanza of the Consolidated Virginia and the California mines. This prompts speculation upon the possibility of opening a similar ore-shoot either within the same property or elsewhere on the lode.

At the time the big bonanza was first worked, the two companies were separate corporations, though practically under the same management. The Consolidated Virginia claim was 710 ft. long, and the California 600 ft., making in all 1310 linear feet of the lode. The two companies were consolidated in 1884; the corporation is known as the Com. Virginia Mining Co. Since the bonanza lay in several closely connected lenses between the two claims, and even extended into the Ophir, it will be treated and discussed as one orebody.

During the year 1877, at the height of production,

ago on the levels where ore is now being found. The policy of the management at that period was to abandon the upper levels and to scatter development work between the 2500 and 3100-ft. levels; this has proved a mistake. It may take another 25 years of prospecting to prove or disprove the existence of ore in paying quantity, and to mine what is known to exist above 3250 ft., the vertical depth of the Combination shaft. To understand the reason, the following observations are made: The Comstock lode is from 100 to 250 ft. wide for the length of the main stem (without the branches), that is, for a distance of about 11,000 ft. Of the 20 principal companies that have operated on the main stem, all but two or three have had bonanza orebodies within their respective boundaries at some stage of their development. Some have had both a shallow (down to 500 ft.) and a deep (below 1500 ft.) bonanza. For the present, only the north-end properties, that is, those lying north of the Best & Belcher, are in a position to profit by the unwatering of the lode as far as it has gone; it will take several years for the remaining properties to be similarly benefited. The great extent of the lode, combined with the inability of 356,883 tons, with an average assay-value of $127.52 per ton, were hoisted through the two shafts, or about 1000 tons per day for the period. A careful compilation, made by the writer, from data taken from the annual reports of the superintendents for each year up to 1882 has been made of the product of the big bonanza, and is presented herewith graphically; likewise the production of the mine from 1883 to 1903, or during the period when it was supposed to have been worked out, was compiled from the official records and is shown in a similar manner. The dividend line of the latter period is omitted, the total figure only being given, owing to the difficulty of obtaining the extended figures.

Statistics are generally uninteresting, but the above summary of the production of the remarkable body of ore cannot fail to attract the interest of mine managers and engineers of today; they are given without apologies.

Eighty-four per cent of the product came from the first workings, or before the mine took fire in 1881, and 16% from the surrounding lower-grade ores, but principally from beneath the bonanza. Since the price of silver was near its coinage value during the
greater part of the time while this 84% was being produced, the actual returns in money from the mines were close to its gross yield. The assessments levied have been heaviest during recent years, and the larger portion of the money has gone to the Pumpsing Association, in payment of each mine's share of the expense of unwatering the lode. The work of the Association on the north end has been concentrated at the C. & C. shaft. The mine had no ore until 1873, the vein within the boundaries of the two claims having 'pinched out' in the vicinity of the 1200-ft. level; hence the early assessments.

On examining the table it is seen that, subtracting the net dividend from the yield per ton gives a cost of $28.82 per ton for the first period, and $20.91 per ton for the second period, which figures include mining, exploration, ore-treatment, equipment, management, and fixed charges. This seems excessive, but there were extraordinary physical difficulties to overcome in conducting the work, difficulties that are not encountered in mining smaller veins. The mine-workings of the Comstock are notorious as being the hottest in the world. The mine-waters from the lower depths vary in temperature between 130 and 160° F. Careful observations, covering a period of years, show that the temperature of the lode increases 1° for every 33 ft. in vertical depth. Where rapid production of ore is in progress, such as usually attends the mining of a bonanza, wasteful methods prevail; economical conditions are hard to maintain. The consumption of mine timber was nearly 5,000,000 board feet annually, costing from $25 to $30 per thousand. Milling charges for ore treatment varied from $13 in earlier years to $9 later. In the Comstock mines a great supply of fresh air must be directed against all working faces; the plenum and the vacuum systems are generally used together in depth. As much as 1000 tons of ice were consumed in one year for ice-water underground. Tubs of it are kept at stations and at all resting places for the miners. The labor-efficiency depends, not so much upon the personal equation of the miner, as upon the efficiency of the management in providing air and water. Debilitating as excessive heat may be to most men, there is not to be found a fitter and healthier lot of miners anywhere than those on the Comstock; it is a noticeable feature of the district.

For a correct appreciation of the bonanza as it appeared while being worked, there is no better source of information than the report of the superintendent, James G. Fair, in his annual report to the directors, dated December 31, 1875. Its terseness and brevity when dealing with such large figures and important facts commend it to superintendents of today. What is copied here is taken verbatim. He said, in part: "During the past year, 169,307 tons of ore have been extracted from all the levels of the Consolidated Virginia Mine, and 169,994 tons have been reduced, which yielded $16,731,653.43 in bullion. There are now in the ore-house and at the mills 2983 tons, valued by assay at $478,086. This ore has been taken from the 1200, 1300, 1400, and 1500-ft. levels, including a small quantity which has been gathered in the explorations which have been made on the 1550-ft. level. On the 1200 and 1300-ft. levels the orebodies have not been developed as far as they extend north. On the 1400-ft. level the ore has been explored south 450 ft. from the shaft (meaning the Con. Virginia shaft), and it extends north from the shaft to the northern boundary of the mine. On this level we know the exact width of the orebody. On the 1500-ft. level the ore has been traced south for a distance of 480 ft. from the northern line, and has been thoroughly explored by cross-cuts from the east to the wall. On this level, all the ore is of a high grade, and the width of the body varies from 150 to 320 ft. The ground south of this is entirely unexplored. On the 1550-ft. level, a lateral drift extends the whole length of the mine. Starting at the southern boundary, it runs northerly on the east side of the ore until it reaches a point 400 ft. distant from the northern line, where it cuts through the clay, and thence passes all the way through ore to the northern line. This level is only partly developed. None of the cross-cuts have yet reached the eastern boundary of the ore. The ore on this level is of a better quality than that which has been found on any of the levels above. Its width, I have no doubt, will prove greater. At a point 320 ft. south of the northern line, a double winze has been sunk from this (1550-ft.) level to a depth of 147 ft. This winze has passed all the way through ore of a very high grade, and terminates in ore of the same quality. The sinking of the winze has been temporarily discontinued on account of the increase of water and
our limited means for hoisting. From this level, north of the northern line (meaning in the ground of the California mine, which was just being opened) another double winze has been sunk to a depth of 128 ft., through excellent ore the entire distance, and terminates in rich ore. The developments made by these winzes proves the continuity at these lower depths of the same orebody which exists on the level above, with an appreciation in the quality of the ore."

When Fair spoke of ore "of a high grade," he spoke advisedly, for the succeeding year showed a production of 145,466 tons yielding $114.50 per ton, or $16,657.649, from the Consolidated Virginia, and 127,540 tons, yielding $105.07 per ton, or $13,400,845, from the California, or a combined yield of $30,058.599, out of which $21,600,000 was paid in dividends. The production reached its zenith a year later, in 1877, from the same ore "of a high grade."

Mechanical Loss in Slime Filtration.
The Editor:

Sir—I would be obliged if some of your readers would give some information regarding the mechanical loss of cyanide incurred in operating such slime filters as the Moore, Butters, Kelly, or Burt. By 'mechanical loss' I mean not merely the amount of cyanide retained in the cakes when discharged from the filter, but the total quantity of cyanide used per ton of slime treated, in excess of that which is required to replace the loss due to chemical decomposition. I fully realize the difficulty of generalizing on a subject into which enter so many varying factors, but it may be that some metallurgists who have had an opportunity of operating such slime filters over a considerable period may have in their possession data showing the amount of cyanide consumption attributable to this cause; in which case, I hope that they will let us have the benefit of their experience.

Rivers R. Baildon.

Puebla, Mexico, October 25.

[Among our readers are superintendents able to furnish this information. We hope they will do so, for it is a matter of general interest to those engaged in cyanidation.—Edtron.]

Refractive Angle Determination.
The Editor:

Sir—Your note, under 'Concentrates,' upon this subject, in your issue of September 26, illustrates an ingenious method for determining, in the field with an engineer's transit, the correction for the refraction of the sun with an error which is within the limits of the graduation of the usual field instrument.

I believe that the method I have used for several years for direct observation of the sun is much simpler and more exact, as the errors under normal conditions of observation will rarely exceed two seconds, while ordinarily the error is only a fraction of a second. The formula is as follows: The correction, in seconds, for the normal refraction of the sun is equal to 58 times the cotangent of the observed altitude of the sun's center. Example: the observed altitude of the sun's center was found to be 18° 40'. What is the correction for refraction?

\[
\begin{align*}
\log \cot 18^\circ 40' & = 0.47130 \\
\log 58 & = 1.76343 \\
\log 171.7'' (0^\circ 2' 51.7'') & = 2.23473
\end{align*}
\]

In this instance we have an error of plus 0.9 of one second.

This formula refers to normal conditions of the atmosphere, at sea-level and a temperature of 50°F. However exact the formula may be, this of itself is of little importance when other important factors are neglected. The factor I especially refer to is the elevation above sea-level at which the observations are taken. At an elevation of 6000 ft., other conditions remaining normal, the refraction will be 81%, and at 11,000 ft. only about 66% of what the refraction would be at sea-level. The neglect of this correction when surveying at high altitudes may, under certain conditions, cause an error of several minutes in azimuth and latitude determinations. The corrections for temperature can be neglected in all ordinary field work.

G. E. Keizzie.

Durango, Mexico, October 4.

Corporation Gratitude.
The Editor:

Sir—In your issue of October 24 is a notice of the report of the Tomboy Mines Co., and it is mentioned that a bonus of 1% of the 1907 profits was paid to the former manager, Mr. John Herron. This is an instance where a corporation has not proved ungrateful. The company is deriving its present profits from ground which Mr. Herron had the opportunity to acquire for his own account, but, without being bound in any way to do so, he turned it over to his employers at no advance in price. It is good to see such an action duly appreciated.

Francis Drake.

San Francisco, October 26.

Spelling Reform.
The Editor:

Sir—I am sending herewith a copy of a letter which may interest you. The spelling in particular is utterly absurd, "thru" and "cheque," the ultramodern and the antique, both on the same page, rather tend to throw a shadow over the imposing letter-head.

If these are the lines along which they hope to advance science, I cannot feel justified in sending them my "cheque" for three dollars.

Yours very truly,

Member A. I. M. C.

New York, October 28.

[It is not necessary to reproduce the letter mentioned above, but a reference to the subject will be found on the editorial page.—Edtron.]
BLIND APEX.

The following problem in mining law has been submitted to us:

Given a claim with the outcropping line A B running west from a dike, which cuts off the vein at B. The vein dips a trifle to the west of south, so that the 400-ft. level exists vertically under claim No. 2. The dike dips westwardly to the 400-ft. level, at which point it turns sharply toward the east, as shown in the section.

The rights to that portion of the vein lying to the east of the dike would be determined as follows: If the apex or outcrop of a vein can be traced in claim No. 1 from B to C, and if it can be shown to be the same vein which apexes from A to B, even though its continuity be broken by the dike, the owner of claim No. 1 would be entitled to all of the vein on both sides of the dike that would be embraced between vertical planes passed through the parallel end-lines of claim No. 1 and extended indefinitely in a southerly direction. This would embrace the segment of the vein designated as D E F on the section, as well as all other segments lying between the end-line planes. However, if no apex is found in claim No. 1 so situated as to extend the extra-lateral right of claim No. 1 to the east of the point B, the extra-lateral rights of claim No. 1 would be measured by a vertical plane A G passed through its westerly end-line, and another vertical plane B D passed through B and parallel to A G. The owner of claim No. 1 would be entitled to all that portion of the vein lying between these planes prolonged southerly. Under these circumstances, the owner of claim No. 2 would be entitled to the segment D E F, and, in fact, to any segment of the vein that existed to the east of the plane B D and that was also vertically beneath the surface of claim No. 2. The terminal edge E F would, under these circumstances, constitute a 'blind' apex, which might give extra-lateral rights to claim No. 2, if it were located so as properly to include the apex E F.

Limestone is used for furnace flux in amounts almost equal to its larger application in the form of crushed stone. The value of the material used for this purpose in 1907 amounted to $9,144,489, as against $7,612,692 in 1906, an increase of $1,531,797. These figures represent outputs of 17,119,297 long tons in 1907, and 16,077,202 in 1906, a gain in the latter year of 1,042,095 long tons. The average value per ton increased from 47c. in 1906 to 53c. in 1907, the increase in price, according to the dealers, being due to increased cost of production. Limestone used for building purposes, including rough and dressed stone, sold by the producers, was valued in 1907 at $4,580,226, as against $3,998,631 in 1906, a decrease of $581,595. Indiana ranks first in the production of limestone for this purpose, with an output valued at $2,378,008, or 51.92% of the total building limestone for 1907. The State second in rank in 1907 was Missouri, with an output valued at $538,114. The value of the limestone used in the United States in 1907 for miscellaneous purposes was $1,324,601, this classification including stone quarried and used by alkali works in New York and Michigan in the manufacture of soda ash; salts; stone sold to glass factories in Pennsylvania, Ohio, Missouri, Indiana, Illinois, and New York; stone sold to paper mills, to farmers for burning into lime to be used as fertilizer, to carbo nic acid plants; and also some for the making of whiting and mineral wool.

Cement production in the United States for 1907 is given as follows:

<table>
<thead>
<tr>
<th>Type</th>
<th>Barrels</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Portland cement</td>
<td>14,785,390</td>
<td>$5,992,551</td>
</tr>
<tr>
<td>Natural cement</td>
<td>2,877,700</td>
<td>1,467,302</td>
</tr>
<tr>
<td>Puzzolan</td>
<td>557,252</td>
<td>443,998</td>
</tr>
<tr>
<td><strong>Total</strong></td>
<td><strong>52,220,253</strong></td>
<td><strong>$55,909,851</strong></td>
</tr>
</tbody>
</table>

The figures show an increase in 1907 of 2.4% in quantity and 1.1% in value, the smallest recorded in recent years. In the portland cement branch of the industry, Pennsylvania, with a production of 20,393,965 bbl., valued at $19,689,006, is still the leading State by a large margin. New Jersey, with an output of 4,449,886 bbl., worth $4,738,516, is second; Indiana, with a production of 3,782,941, valued at $4,757,860, is third; Michigan is fourth, with an output of 3,572,688, valued at $4,384,731; and Kansas fifth, with an output of 3,358,925, valued at $4,240,358. These five States contributed almost three-fourths of the total production, and none of the remaining States produced as much as 3,000,000 bbl. during the year.
THE SAN JUAN REGION, COLORADO.—I.

Written for the MINING AND SCIENTIFIC PRESS

By THOMAS L. READ.

In romantic interest, scenic beauty, and general attractiveness, few regions can compare with the roughly circular mountain uplift lying in the southwestern corner of the State of Colorado, and collectively designated 'the San Juan.' About 75 miles in diameter, it includes portions of the counties of Ouray, San Miguel, Dolores, San Juan, La Plata, Hinsdale, Mineral, and Gunnison, and forms a part of the continental divide. From its eastern slopes descend the tributaries of the Rio Grande, which traverses the fertile San Luis valley on its way to the Gulf, while from the gulches of the northern and western borders issue the creeks that join to form the Dolores, the San Miguel, and the Uncompahgre rivers, feeding the Colorado as it sweeps toward the Pacific Ocean.

Profound and accurate reports on the geology and mineral resources of the region have been issued by the United States Geological Survey. Many have written on its early history and development, while none have written more interestingly and entertainingly upon its general features than T. A. Rickard. It may seem, then, a work of supererogation to attempt further description. But the mining industry of a region is like a living organism, affected by the opposing forces of growth and destruction, and no complete description is possible until after its life is ended. It may be worth while, therefore, to note the latest phases of development, including so much of the old as is necessary for a complete discussion. Being a popular review rather than a scientific description, no attempt will be made to credit each bit of information to its source.

Mining began in the eastern part of Colorado in 1859, when the western portion of the State was still inhabited only by Indians. In 1860 an expedition was led by Baker into the San Juan, but the outbreak of the Civil War distracted attention from the district for several succeeding years. An expedition led in after the war was opposed by the Utes, and few white men ventured to enter the region. The beginning of serious development was marked by the discovery in 1871 of the Little Giant vein, near Silverton, by Miles T. Johnson, and the discovery of the Ute and Ulay near Lake City in the same year. When these became known, prospectors flocked into the district and flourishing towns soon sprung up where only Indian encampments had previously existed. Within a few years the production became important. The feature that most hindered the development of the district was its inaccessibility, the cost of bringing out a ton of ore being enormous. At first trails were broken, then wagon roads constructed, and finally the Denver & Rio Grande railroad crept in, skirting the uplift, and sending branches like tentacles into the interior. It reached Silverton in 1882, Ouray in 1887, Lake City in 1889, Telluride in 1890 and Creede in 1891. These branches make the mining districts comparatively accessible, but large areas are still difficult to reach except on horseback in the summer time. A second way of meeting the problem of development was by erecting mills to concentrate the ores. But the ores of the San Juan are in general peculiarly refractory. Even by the more recent methods of milling they are difficult to treat. As a rule the extraction was low except in the case of the free-milling gold ore. The third method was that of smelting in local plants. Many of these were erected in the early days. But the obstacles encountered were even greater than those in milling, and after a more or less brief existence all were closed except the Durango plant of the American Smelting & Refining Company.

The richest ores were mostly confined to the upper oxidized portions of the veins. The poorer ores found in depth required considerable metallurgical skill to be handled at a profit, and the processes necessary were not simple enough to be applied economically on a small scale. As a result many of the smaller properties were closed when the lean ores were reached. Consolidation of interests in certain cases made possible the working of the mines upon an adequate scale. The district accordingly first enjoyed a period of intense activity, followed by a period of depression, aggravated by the great fall in the price of silver in 1893. This depression is now being succeeded by a steady growth, with sufficient capital to overcome the difficulties of working the deeper ores.

The central core of the San Juan uplift consists of ancient granites, gneisses, and schists; these are exposed in the valley of the Animas river on the south, and in the Uncompahgre plateau to the north; they are supposed to be of Archean age, but it has not been proved that they are older than the thick series of quartzites that appear near Ouray and in the Needle mountains south and east of Silverton. These latter are generally regarded as being of Algonkian age, and on their upturned edges the Paleozoic sediments lie unconformably. The oldest Paleozoic rocks well represented are Devonian limestones, exposed in the Animas valley and at Ouray. It is an important terrain for ores. These in turn are overlaid by a thick series of carbonaceous limestones and calcareous sandstones. Succeeding these is a Permo-Carboniferous series, overlaid by reddish conglomerates, sandstones, and limestones of Triassic age. These are followed by Jurassic beds and then comes the Cretaceous beds from the Dakota up to the Laramie. Minor unconformities exist in the Paleozoic and Mesozoic sections, but in general they dip to the northwest, west, and southwest at moderate angles. In the eastern part of the San Juan the Paleozoic rocks are entirely absent, the Cretaceous resting directly on the granites and gneisses, and for the most part only the Tertiary volcanics are exposed. The volcanic rocks consist of lavas, flow-breccias, and tuffs, usually andesite, but exhibiting all gradations from rhyolite to basalt, aggregating an enormous thickness, of which no accurate estimate can be
made. In the eastern portion these constitute the whole section; to the west they overlie the Cretaceous, where they have not been removed by erosion; and on the extreme southwestern border they are perhaps in turn overlain by Tertiary sediments. The stratigraphy of the region is far from simple, and to obtain an adequate knowledge of it, reference should be made to those geologic folios of the U. S. Geological Survey in which a large part of the area has been mapped. The position of the vents from which the volcanic materials were ejected is not known, and many other geologic problems remain unsolved.

The Tertiary disturbance gave rise to extensive fissuring, sheeting, and zonal shattering that furnished places for ore-deposition, while the magmatic and other waters, similarly stimulated in their circulation, brought in the metals. Almost every type of deposit except segregation from an igneous magma can be found somewhere in the area, but fissure-veins and replacements are most common and important. The ores generally contain lead, zinc, silver, and gold, with subordinate amounts of copper, but some of the largest and best known producing mines are chiefly valuable for gold. The ores are confined to no particular zone, but occur throughout the entire geological section. At Creede and Lake City, for example, the ores are entirely in the volcanic rocks. Near Ouray the ores are distributed from the Cambrian almost to the top of the Cretaceous, while a few miles south, at the Camp Bird mine, the ore-zone is again in the volcanics.

Stream erosion and the action of glaciers have combined with landslides and faulting to produce a region having scenic beauty only rivaled by its geological interest. The region is actually a unit, but stream-dissection has so divided it that separate names are given to different portions, as, for example, the Needle mountains. Throughout the area lofty peaks are separated by deep narrow gorges, so that

Fig. 2. Alpine Gulch, near Lake City.

Fig. 3. A Landslide Block.

Fig. 4. Willow Gulch, near Creede.
the topography is extremely varied. The larger number of peaks approximate 14,000 ft. in altitude, having shared in the earlier penneplanation, as is suggested by the closely similar elevation of all the more important mountain summits throughout the State. The mountains as a rule afford ample evidence in their denuded surfaces of glaciation, while among the commonest features are the glacial cirques, generally known as 'craters,' with the typical lake below, as shown in Fig. 1, taken from the top of Wood mountain, the lake at the foot of the cirque being 2000 ft. lower. Terminal and lateral moraines are common. A conspicuous terminal moraine can be seen on the San Miguel river a few miles below Telluride, just above where the Lake fork joins the main stream. Stream cutting has often altered the glacial topography, as shown in Fig. 2, looking up Alpine gulch toward Red Cloud peak near Lake City. In the bottom of the U-shaped glacial valley the stream has cut for itself a deep gorge. Another striking feature of the topography consists in the frequent 'landslide blocks,' one of which is shown in Fig. 3. These landslide blocks are frequently of large extent. In the southwestern portion of the San Juan a mine was developed in what subsequently proved to be a landslide fault-block, and the original position of the vein was never discovered.

Creede is the principal town and county seat of Mineral county, and is also the youngest of the mining camps of the San Juan. The camp dates from 1891, when the Denver & Rio Grande railroad was built to this point, and the rich silver ore of the Holy Moses was discovered by Bill Creede. Other discoveries followed, and the production for 1892 had a value of about $3,500,000, the total production previous to that year amounting to about $150,000. It seems strange that the camp remained so long undeveloped, for it lies near what was for many years the main line of travel and freighting between the eastern part of the State and the San Juan. The packers started from Fort Garland in the San Luis valley, followed the course of the Rio Grande river, and turned to the left below Creede through Antelope Park to Lake City, Ouray, and Silverton. Singularly, too, the original discovery, though possessing some exceedingly rich ore, was never a source of much profit.

All the mines are within a radius of two miles from the junction of the east and south branches of Willow creek, a few miles above where it flows into the Rio Grande. The character of the ores has changed markedly in the 15 years since the district was opened. The upper portions of the veins were extremely silicious, and rich in silver. With increase in depth the silver content has become less important, while galena and zinc-blende, with a variable but not inconsiderable amount of free gold, have become the valuable constituent of the ores. Consequently the region has largely changed from a shipper of crude ore to a producer of milling ore, although the total shipments are still in excess of the output of concentrate. The shipments for 1906 were 38,600 tons of crude ore and 31,600 tons of concentrate. The value was over $1,000,000 in silver, nearly a million in lead, a little less than a half million in gold, and about a hundred and fifty thousand in zine.

Looking nearly east up Willow gulch from the town of Creede (Fig. 4), one sees in front and to the left Campbell Mtn. rising from the forks of the stream. East Willow creek, where the original discovery was made, is to the right. Farther to the right rises the slope of Mammoth Mtn., which overtops Creede. At the extreme left is the slope of Bachelor Mtn. The rocks are a complicated series of porphyries and flow-brecceas, generally andesitic; they stand nearly vertical, and are much sheeted by pressure, and so crumpled and thrown into folds as to make their true relation difficult to distinguish. The veins generally fill fissures or sheeting-zones in the volcanics. The larger part of the present production comes from the Bachelor vein, which extends from near the junction of the two branches of the creek in a direction a little east of south for over two miles. Except in width and persistence it is representative of the veins of the district. It varies from 8 to 40 ft. wide, and dips 59° west. The hanging wall is trachyte and the foot-wall is porphyry. Included within the vein-filling are masses of the country that have usually been converted by the action of the waters to a chloritic or talcose material, but when broken open often show a core of the unaltered eruptive. Kaolized masses are not wanting. The chief mineral in the lode matter is silica, and when crystallized it is amethystine, but when chaledonic it is white or yellow. The veins are 'vuggy,' and cavities lined with druses of well developed crystals are extremely common. The galena may be coarsely crystallized or fine-grained and steely; the amount of zinc-blende seems to be increasing in depth. The gold appears to be chiefly associated with the zinc-blende; it is free and rather fine; in milling, it may be seen in a thin lining coming off at the head of the tables. Pyrite is subordinate in amount and chalcopyrite, though not noticeable, is present, as now and then shipments of concentrate rise as high as 20% copper. Barite appears to some extent in the south end of the vein, but is absent from the northern portion. The abundant presence of manganese is shown by its black oxides and in the amethystine color of the quartz.

The Bachelor vein is opened up for 10,000 ft. by an adit known as the Nelson or Wooster tunnel. It intersects the workings of the Happy Thought mine on the 1300-ft. level. The New York, Del Monte, Last Chance, and Amethyst are all on this vein, and operate through the adit. The Commodore mine, shown in Fig. 5, is operated through its own adits by a leasing company, which is the largest individual shipper of crude ore in the camp. Creede is typically a lessee's camp, the only concern operating mine and mill on its own account being the East Willow Co., owning the Solomon mine. The largest lessee is the Creede United, which operates a number of the properties on the Bachelor vein, and the Humphreys mill in Willow gulch. Four mills are in operation, making galena and zinc concentrate. In
the Humphreys mill the average mill ore assays 8 to 9% lead, 2 to 3% zinc, and 0.10 to 0.12 oz. gold, with a subordinate amount of silver. The milling practice in outline is to crush by rolls to 4 mesh or finer. The sized product goes to four-compartment jigs. The hutch work from the first two compartments is ready for shipment as lead concentrate. The hutch work from the second two is re-ground in Bryan mills. Both the re-ground product and the fine from the rolls are classified and treated on Willey tables, which make lead concentrate, zinc middling, and tailing. The zinc-middling goes to a second set of tables which makeslead concentrate, zinc concentrate, and tailing. The tailing from all the Willeys flows to waste over canvas tables, where some silver is caught. It is found best to throw more zinc into the lead concentrate than would otherwise be necessary for the purpose of preventing gold from getting into the zinc concentrate, as the zinc smelters do not pay for the precious-metal content. Even then it is found easy to keep the zinc in the lead concentrate below 10% and the lead above 60. One mill cleans its zinc concentrate to 60%, but this leads to excessive loss and is not to be recommended.

The mills are worked by water-power during the summer, but in winter it is often difficult to obtain even enough for milling. Several of the mines operate aerial tramways. One of the most interesting of these in the State is that of the Kentucky Belle, which descends in a clear span of over 1500 ft. at so steep an angle that the only convenient way to see the upper terminal is to lie on one's back.

From Creede, by the old freight trail it is but little more than 25 miles to Lake City. It may be ridden on horseback in a day, but to go round by rail consumes 2½ days. By railroad the traveler goes down the Rio Grande to Alamosa, thence north up the fertile San Luis valley, past the old Orient iron mines, once the principal producer of the Colorado Fuel & Iron Co., and over the Poncha pass to Salida, where is situated the 350-ton plant of the Ohio & Colorado Smelting Co. The trip is then made over Marshall's pass and down the canyon of the Gunnison as far as Sapinero, where a branch line extends up Lake Fork to Lake City. The canyon of Lake Fork is only surpassed by that of the Gunnison in beauty, and its physiography is replete with interest. Lake City is one of the old towns of the San Juan, having been founded in 1872. It is situated at the junction of Henson creek and the Lake Fork in a broad flat valley. Once prosperous, the town now wears an air of dejection, an effect that is heightened by the wretched hotel accommodations. Scattered about are the remains of defunct smelters, while the mills in the neighboring gulches are mostly closed down. Many important mines became lean in depth, and the ores near Lake City are more difficult to mill than those from other parts of the San Juan. The fate of local smelters in so remote a district was, of course, sealed from the first.

The chief activity at Lake City is now due to properties farther up Henson creek near Capitol City, where the Highland Boy, the Independence, and Yellow Medicine are shipping ore. The first mine at Lake City was the Ute & Ulay. Another famous producer was the Golden Fleece. The mill, now idle, is shown in Fig. 6. The ore deposits around Lake City have been described by Irving. The rocks at Lake City are a confusing series of flow-brecia, tuff, and porphyries, which stand at high angles, and are frequently much sheeted and intruded by later eruptives. The veins fill fissures that dip from 45 to 60°. The ores contain sulphides of lead and zinc, with subordinate amounts of pyrite and chalcopyrite, the chief value being in the silver associated with the tetrahedrite or gray copper. It is this which makes the ore so difficult to mill, as the tetrahedrite slimes so readily. This argentiferous slime is most difficult to save. At the Golden Fleece the silver was in the mineral petzite. This was even more difficult to mill, and the extraction was so small that when the high-grade ores were exhausted the property was obliged to close.

"J. D. Irving, Bulletin No. 260, U. S. G. S."
MR. MURPHY ON SLIME FILTERS.

Written for the Mining and Scientific Press.
By An Occasional Contributor.

"'Tis a traymininous rockshun th' la-ads all do be havin' in th' pap'rs these days as t' which wan iv thim is th' best hand at ca-ake makin'," said Murphy one day, as he was waiting for quittin' time.

"What do ye mane?" asked McCarthy.

"Why! haven't ye bin ra-adin' me frind Rick-a-ard's pap'r lately? An' ye a good an' th'irty scab. I'm surprised at ye!" said Murphy.

"'An' d'th' wos in th' afternun' I was at the plant, he says. "An' t'is says, 'An' th' sys-tem is as t' best nonent,"' said Murphy.

"Ye'd think 'twas afternun' th' iv th' municipal congress ye were ra-adin' abo. 'Ye must not mix too much wather, says th' wan, 'Ye must use Moore-Butcher!' says another. "An' serve it with a leg-o-lamb," says a third; an' so on. An' thin' th' little Englishman with th' two fir-est names lets out a yell, an' says, 'Ye are all iv ye don' it th' wrong way,' he says. "Th' right way's th' Ridgway," he says, 'an' I'll prove it t' ye. 'Tis me obnissed perfeshunal opiniun, he says, 'an' what more could ye want? That th' Ridgway's th' only way, if ye are t' do it right,' he says. "All I ask iv ye is t' ta-ake a look at me pa-atty-ca-ake masheen, which is in success-ful operashun at th' South Pole, an' he convinced, he says. "An' thin' give ye yeer orders f'r a few iv thim," he says.

"An' thin one iv th' ither la-ads makes a few quiet raymar-rks that ye could hear in South Afriky. "Ye must pa-ay no attenschun, 'r money aither, 't th' rist iv thim," he says, 'f'r if ye do ye-er no frind iv mine," he says, 'an' I'll have th' law on ye, he says.

"An' I mane it, f'r me lawyer has daysided in me favor all th' suits that I am about t' start agin' th' ither la-ads," he says. "Me sys-tem iv ca-ake makin' is th' best anyhow, an' th' cha-apest," he says. "I'll cha-arge ye only tin dollars a ton r'yalty, an' will let ye daysign an' build ye-er own pla-ant," he says, 'an' let ye nse me frind Clancy's cha-arm t' ma-ake it wor-rk," he says. "An what more could ye want?"

"An' thin anither la-ads has his say. 'Niver moind what anny iv th' rist iv thim tell ye," says he, 'f'r 'tis a lie," he says. "Me own sys-tem's th' best, f'r I'm a rale invinter," he says. "An' he is, McCarthy, f'r wan day he was goin' an' an' he saw a felly screwin' up a bolt with a monkey wrench, an' he had a gra-ate idea. 'I'll invint," he says, 'a monkey wrench f'r oussrewin' bolts," he says; an' he got a patent on it. After ye die, McCarthy, an' git out iv purgatory, an' git ye-er ticket all straightrtened out with Saint Pether, an' th' cha-ange counted, ye will observse as ye sta-art f'r th' Ga-ates, that they look annatural some way, an' as ye git clothyer ye will find that they have bin turned upside down, an' that our frind Charley is collectkin' a r'yalty on ivery wan that enthurs.

"But th' fray continues, an' th' ither la-ads all jump in an' jine it, some on wan uth' other some on th' ither sides. 'Ye-er a liar," says wan. 'Ye-er anothar," says th' rest."

*I to the Editor: This may seem unnecessary, but I was tempted to put it in, as, about the time of the Haywood trial, we found some copies of the Mining and Scientific Press in our reading-room, marked, "This is a scan paper."

"I wouldn't letannywan iv thim call me a liar," said McCarthy.

"How could ye help it?" replied Murphy, "if there be three Sta-ates an' th' Gran' Canyon be-twane ye? 'Tis safe enough that way."

"Me frind Charley gits tired iv th' fracas though, finally, so he calls up his la-ads an' tells thim t' ma-ake th' uthers shut up. 'An' if ye don't write articles I c'n ra-yfer to with pr-ride, I'll fire th' bunch iv ye,' he says. They do th' best they can, but 'tis a ha-ard job he has given them.

"An' thin, be way iv dayvasion, th' sole an' original invinuters iv th' self-actin' tube-mill linin' sta-arterd a rumpns iv th' r own. It soon dayveloped into a grute riot, an' th' poleece were powerless, as they were outnumbered two t' wan, an' they had t' call out th' idaytorial nesnal ga-ard. A cons-li-tayshun was held, an' 'tis daysided t' char-rge th' la-ads reglar advertizin' ra-ates f'r all they say. 'Tis a gra-ate success, I f'r not wan iv thim could raise th' price."

"What's th' use iv all th' scrappin', anyhawn?" asked McCarthy.

"Well, it's this way," said Murphy. "Ye see, there be a lot iv la-ads that want t' git fa-am, but onless they have a chance t' ballk when there's a fight on, it's ha-ard f'r thim to attract attenshun."

A SAND-TANK SAMPLER.

Written for the Mining and Scientific Press.
By H. W. MacFarren.

The sand tailing at the Pittsburgh-Silver Peak Gold Mining Co.'s plant at Blair, Nevada, is leached in tanks 36 ft. diam. by 111/2 ft. deep, holding approximately 500 tons. The problem of sampling a charge of this depth has been met by a sampler of simple design. A piece of 11/2-in. pipe, 13 ft. long, is taken, and 4 in. of one end is tapered to a closed point, while the other end is threaded for a four-way pipe connection, admitting of two short lengths of pipe being screwed into the cross to form a handle. A slot 3/8 in. wide is cut the length of the pipe, beginning just above the tapered end. This is approximately 111/2 ft. long. One side of the slot is bent slightly inward, while the other is flared out ward and filed down to a cutting edge. A collar is placed on the pipe near the handle, to indicate when the sampler has been plunged sufficiently deep into the charge. Two men are required to manipulate the sampler with ease, on account of its length, although it is possible for one man to use it. A long wooden pole is first inserted into the pipe, completely filling it, and the sampler is worked into the sand close to the canvas. The wooden pole is then withdrawn, and the sampler is revolved, so that the cutting edge of the slot will fill the pipe with sand, and the sampler is then withdrawn. The sample is tapped out into a long receiving box.
SMELTING AT CERRO DE PASCO, PERU.

Written for the Mining and Scientific Press
By Lester W. Strachan.

La Fundicion de Tinayhuareo, better known as the Cerro de Pasco smelter, is the largest plant of its kind in South America, and stands at the highest altitude, 14,000 ft. above sea-level, of any smelter in the world. The plant, together with the coal and copper mines and the railway, forms the basis of an important enterprise controlled by American capital. The management, since March, 1907, has been vested in R. II. Channing, Jr., formerly of the Utah Consolidated Co. The Cerro de Pasco Mining & Railway Co. was organized in June, 1902; it was recently re-organized and re-capitalized, to settle an expensive drainage lawsuit in Peru. The old company holds 95% of the stock of the new company.

The properties are situated in the Department of Junin, Peru, and accessible from the coast (port of Callao) by the Central Railroad of Peru to Oroya, going from sea-level to an altitude of 15,665 ft., at the Galera tunnel, under Mount Miegg. The line to Oroya is single-track, and is probably one of the most remarkable railroads in the world, having a maximum grade of 4%, with about 18 switchbacks, and going through 60 tunnels. The Cerro de Pasco line, also single-track, has only one switchback, no tunnels, and a maximum grade of 2\(\frac{1}{4}\)%.

The run of 82.7 miles is made in 3\(\frac{1}{2}\) hr., including stops. The accompanying sketch map shows the relative positions of the coal and copper mines and smelter. The coal mines, located at Geyllarisquisga, are 47 kilometres (29.4 miles), on a branch line from the smelter. They furnish about 20,000 short tons of run-of-mine coal per month, delivered in 50-ton steel
hopper-bottom cars. The railroad is also standard-gauge single-track, with maximum grade of 2½%. The coal is bituminous, rather high in ash; the mines are not "gassy." Coal is also mined at Vinehuscancha and Quishuuracancha.

The larger part of the ore smelted comes from the Cerro de Pasco mines, 14,300 ft. above sea-level. The ores occur on a contact between andesite and overlying limestone. They are somewhat soft and break down readily to fines. Considerable timber, shipped ready framed from Oregon, is used in the mines; the caving system is being adopted where feasible. Machine-drills are being used for stopping and development work. Four shafts have been used for hoisting the ores, but three of these are being replaced by one central shaft. The ore is screened, after delivery on the surface, through a ¾-in. grizzly. The steam-plants for the hoists will be replaced by electric power. The present monthly ore production is 18,000 tons, delivered to 50-ton steel hopper-bottom cars. Part of the ore smelted comes from the Morococha district, 186 kilometres (116½ miles), by rail, south-west from the smelter. The ores smelted are principally sulphides, pyrite, chalcopyrite, galena, zinc-blende, and tetrahedrite, with some oxidized ores, such as malachite, chrysocolla, and azurite, in a silicious gangue; the Morococha gangue is aluminous. The Cerro de Pasco ores vary from 4 to 15% copper, 3 to 10 oz. silver, and 4 to 13% lead; the Morococha ore varies from 9 to 11% copper, 10 to 15 oz. silver, with no lead. These figures are estimates.

At the smelter the operations are entirely under the supervision of the general superintendent, S. J. Gormly, aided by an assistant superintendent. The various departments about the plant are headed by competent men, the whole forming a harmonious unit. On furnace work the 8-hr. system is in vogue, each shift being in charge of a general foreman, who supervises all the furnace work, its accessories and converters; shifts are changed every month. For experimental work there is an experimental chemist; in the laboratory the head chemist reports all daily determinations. The working day begins at 8 a. m. and ends at 6 p. m., with one hour for the midday meal.

About 1400 tons of ore, lime-rock, and coal are run in daily, weighed, and delivered to their respective bins; the ore to be sampled being deposited in the steel hopper-bins behind the sampling-mill; and the coal, except that for the power-house, which is dumped there, being delivered to the bins at the coal-washer. The ore-bins are flat-bottomed, steel-framed with wooden lining, having a total storage capacity of about 15,000 tons; the lime-rock bins are of similar type. The charge cars, of the same type as those used at the Washee (Montana) plant, are loaded with 2.5 metric tons (2.75 short tons) of charge-ore and flux, and are made up in trains of six cars; they are spotted and switched about by Dav-enport locomotives. They have proved satisfactory, not giving much trouble from steam or smoke, and form a flexible system, which is impossible with electric motors, where burning-out, short-circuiting, and so forth, would be costly as well as dangerous. Compressed air would be more costly than the present system.

The eight Babcock & Wilcox boilers are rated at 400 hp. each, under a pressure of 150 lb., and are hand-fired, using about 180 tons of run-of-mine coal daily; the ashes are run to the waste pile, or used as railroad ballast. Natural draft is used, the chimney being about 180 ft. high and 12 ft. diam. inside. The power-house immediately adjoins the boiler plant. There are two Nordberg cross-compound engines, 16 by 32 by 36-in.; 550 hp. each, making 120 rev. per min., driving two alternating current dynamos of 440 kw. each. These supply the electric power used. Three Root blowers, No. 11, running at 120 rev. per min., giving 350 cu. ft. per rev. at 24-oz. pressure per square inch to the blast furnace, or a total of 126,000 cu. ft. per min., are individually driven by a Nordberg tandem-compound Corliss engine, 15 by 30 by 36-in., using a 16-ft. flywheel and taking 450 hp. A Nordberg cross-compound blowing engine, 27 by 54 by 60 in., making 68 rev. per min., requiring 800 hp., supplies 12,000 cu. ft. of air per minute at 17 lb. pressure per square inch to the converters. A duplicate of this is being erected. A Nordberg duplex air-compressor, 18 by 18 by 42 in., supplies air at 70 lb. pressure to air-lifts for opening charge-doors, unloading charge-cars, and the like. A new two-stage Nordberg compressor, 14 by 27 by 15½ in., with 42-in. stroke, is being erected. For emergency lighting, there is a 14 by 14-in. Ball automatic cut-off engine, making 250 rev. per min., connected with a 3-phase, 75-kw., 2500-volt, alternating-current generator. There are two exciters; one a 11 by 11-in. marine-type engine, making 280 rev. per min., connected with a 50-kw. 125-volt direct-current machine, and the other a 10 by 24-in. Corliss engine, making 120 rev. per min., connected with a 50-kw. machine of the same type as the above. For supplying hydraulic pressure to the converters, two 14 by 7 by 15-in. outside-packed trombone-style pumps give 300 lb. pressure per square inch; two of the same type of pumps are used.
for feed-water to the boilers. The boiler and machine shops are fitted up to do all repair work for the mines, smelter, and railway. The foundry is equipped with a 50-ton Whiting No. 5 cupola, a No. 6½ Root blower, and a 10-ton electric crane. Considerable custom work is done in the shops. The company is able to repair and completely equip the 50-ton consolidated 8-driver and 19 by 26-in. cylinder Mogul type locomotives. The switching engines are the Davenport type, 9 by 16-in. cylinders, carrying steam at 150 lb. pressure per square inch; a new type of engine will shortly be used; and also a 45-ton saddle-tank, with 4 drivers and 18 by 22-in. cylinders. Besides the carpenter shop, there is a pattern and turning shop.

The water supply is brought from a lake about three miles distant, using an inverted siphon one mile long. To insure a sufficient supply of water a pump-station has been erected, about 1.5 miles from the plant, which will pump about 1000 gal. per min. from a small stream to a ditch leading to the smelter. At present about 2500 gal. of water are being used per minute. A master mechanic is in charge of the machinery and shops above mentioned; he is held responsible for the continuous running of the plant. Each department under him is in charge of a foreman.

The sampling-mill is equipped with three Vezin and one Bridgeman sampler, each taking 1/2 cut. The accompanying flow-sheet shows the process involved to produce the final sample. Each ton of ore yields 3.2 lb. of sample, that is, 0.16%. The final sample, reduced to 1/8-in. size, is quartered, then crushed in laboratory rolls, cut down on riffles, pulverized in a Braun pulverizer, and passed through a 120-mesh screen. All samples for the laboratory are reduced in the mill, placed in paper sacks, marked, and sent to the chief chemist. The "rejects" from sampling are elevated and screened through a 1/2-in. grizzly, the fines going to the reverberatory, and the course to the blast-furnace bins. The capacity of the mill is about 200 tons per 10 hr. Every third car from the mine is sampled. Shaking-feeders deliver the ore to each sampler.

(11) Pulping and quartering for analysis.

The coal-washer makes two commercial products: steam or nut coal (3/4 to 1 1/2 in.), used for the reverberatory furnaces and for the Davenport engines; and coking-coal and 'sludge' (finer than 3/4 in.), used to make coke. The plant has a capacity of 350 tons of run-of-mine coal per 9 hr., running only on day shift, recovering 70% of the coal washed, that is, a finished product of 250 tons of nut or steam-coal and coking-coal, and sludge, and 100 tons of waste. Electric motors are used to drive the machinery, about 135 hp. being consumed. The supervision of the washer and coking plant is under a capable superin-

![Reverberatory Furnace, Cerro de Pasco Smelter.](image1)

![Converter Floor and Crane, Cerro de Pasco Smelter.](image2)
tendent. The Williams disintegrator, with a capacity of 500 tons of coal per 10 hr., is replacing a toothed roll, 25-in. diam. and 30 in. face, which required considerable repairs and caused breakdown. The jigs are of the Luhrig type, each with single compartment. The fine-jig compartment is 42 by 53 in., and the coarse 38 by 51 in.; feldspar pebbles are used for bedding. The launder system, for the several finished products, is flexible, so that the washed sizes can be diverted to bins according to demand. The clear water from the settling-tanks is pumped back for re-use, practically clear, with a 10-in. Worthington centrifugal pump. Pyrite occurs in the coal, but does not appear to much extent in the finished products. The washer tailings are run to waste, or run to railroad cars, to be used for ballast. The coking-coal and sludge is delivered to a double standard Connellsville side-dump larry, holding 9 tons, which is hauled up an incline above the coke-ovens. There is from 5 to 12% moisture in the product as charged into the ovens. The ovens are arranged in series of 35, back to back, making 70 ovens in all. They are of the bee-lhive type, 12.5 ft. diam. and 8 ft. high, inside measurements. This type of oven is decidedly wasteful with the kind of coal coked. By-product ovens would afford use of the gases, would give a better coke, with less wear and tear on the plant, although requiring more capital for erection. Each oven can produce 3.45 tons of coke per 48 hr., the time required to coke a charge of 5.8 tons of coking-coal and sludge; about 60% of the charge is recovered as coke. The escaping gases are not used. The coke is granular, fairly porous, strong, and obtained in lumps as large as 20 by 12 by 5 in.; it remains intact until reaching the zone of fusion in the blast-furnace. From 100 to 120 tons of coke are produced daily. Hand labor is used entirely.

In the washer the coal products are sampled every hour, taking ‘grab’ samples. These samples, together with coke samples, both domestic and foreign, are analyzed every 10 days. The following analyses are representative:

The ash contains about 69% SiO₂, 28% Al₂O₃, 9% Fe₂O₃, and 3% CaO and MgO.

All the bricks used, both fire and silica, are made in the local plant, distant some 10 miles from the smelter. The silica-brick contains about 98% SiO₂, with small amounts of Al₂O₃, Fe₂O₃, and CaO; it has stood the water-test better than the imported brick. The fire-brick contains about 60% SiO₂, 35% Al₂O₃, with a little Fe₂O₃ and CaO. The size of brick made is 9 by 4.5 by 2.5 in., and 12 by 6 by 2.5 in.; silica bricks of the former size are being used for the side walls and the latter for the roof of the reverberatory.

The plant occupies a terraced hill-site. All the buildings are steel-framed, covered with corrugated iron. The blast-furnace building, directly in front of the ore-bins, contains the furnaces and converters. The four furnaces are arranged with their longer axes parallel to the length of the building. Three are 56 by 180 in. and one 50 by 180 in. at the tuyeres. The smaller furnace does not drive as well as the others, probably on account of its narrower width. From the centre of the tuyeres to the charging-floors is about 18 ft., but the height of the charge, to the top of the lower jacket, is only 7.5 ft., owing to the presence of fines in the ore. Each furnace has 12 jackets, with a water-space 5½ in., four to each side and two to each end, and a tap-jacket with a 2-in. water-space. There is one foot of bosh to the total height of the side jacket, and there is no end bosh. The cruceible is supported by short latticed posts, resting on a concrete foundation; silica bricks are used for the bottoms. The settlers or fore-hearths, five altogether, are 16 ft. outside diameter and 5 ft. high. The matte and slag enter the settler continuously on the side adjoining the furnace, the latter flowing away at right angles on the side opposite the matte tap, to its entrance, where it is granulated and swept away by a water-jet. The slag-launer is a 12-in. channel-bar, with sheet-iron sides. Close to the dumping-ground is a de-watering arrangement, whereby part of the water flows to an air-cooling tower, to be pumped back by two centrifugal pumps. About 60% of the water is returned. With the large volume of settler, ample storage-capacity is obtained for the matte, according to the demands of the converter; the sides of the settlers are encircled by a water-pipe spraying water continuously. Only two settlers are used for the four furnaces. The matte is sampled as it enters the matte-ladle.

The tops of the furnaces are closed, the fume passing off through elbow down-takes on two furnaces, and through old-style flues with hopper-bottoms on the other two furnaces, the fume going to the dust-flue, and thence to the dust-chamber. The dust-flues, made of brick, are 10 by 12 ft. in cross-section; the dust-chamber is 20 by 28 ft. in cross-section, and 200 ft. long, connecting with a steel stack 220 ft. high and 22 ft. outside diameter. Previously it was necessary to shut down the furnaces to clean the flues; a new flue has been made by tunneling under the old one, which will be provided with pyramidal hoppers, that will be discharged by an ingeniously devised spout, the flue-dust passing to a belt-conveyor. This spout has two gates, with slots cast at an angle of 90° to each other, connected with a rod operated by a hand-lever; one turn opens the upper gate, admitting the flue-dust, while the lower gate is closed; another turn closes the upper gate and opens the lower, permitting the flue-dust to fall upon the conveyor. With this scheme the operator does not suffer from the gases and dust, while the furnaces can be run and the flues cleaned.
without interruption. Forty-four of these spouts will be used. Up to the present time the amount of flue-dust made has probably been 10%. There are 14 tuyeres to a sile on each furnace, no end tuyeres being used. The tuyeres are 4 in. diam. and are set 12 in. centre to centre. On an average four tuyeres are cut out continually on account of accretions. Punching at the tuyeres is done as occasion demands; as a rule not much trouble is experienced. The blast pipe, 2 ft. diam., extends along the sides of the furnace, branching off from the blast-main. Each furnace has its shut-off gates. About 400 cu. ft. of air per minute are used per square foot of hearth-area at the tuyere-level.

Two charge-cars are usually dumped at a time, by an air-lift, on alternate sides of the furnace every 25 or 30 min., depending on the running of the furnace. Coke is fed first, followed by the ore and flux from two-wheeled buggies, each holding about 225 kilos, the amount varying from 9 to 11% of the charge. At present only domestic coke is being used. Foreign coke is being accumulated to the extent of several thousand tons, in case the production of the domestic coke should be interrupted. From 90 to 110 tons of the latter are used daily, while 70 tons of the former would suffice, so that the foreign stock alone will amount to more than a month's supply, aside from the domestic coke accumulated. The empty charge-cars, after leaving the furnace, are spotted under the converter slag-bins, where air-operated gates discharge the approximate amount of slag; the train is then run to track-scales and the contents weighed. Ore is next charged from bins, the gates being operated by a hand-lever mechanism, and cars weighed; lime-rock is charged last, and the cars weighed. The charge, when dumped, distributes the course to the walls and the fine to the centre of the furnace, which tends to good running. About 15 to 20% of the ore and flux charge is lime-rock, 20% converter slag, and 60 to 65% ore. The temperature of the escaping gases at the stack varies from 180 to 350° C. A charge of two cars is dropped in less than two minutes, so that the fall in temperature due to opening the charge doors is not important. SO₂ gas is often plentiful on the charging-floor, depending from which direction the wind blows. About 75% of the sulphur is volatilized. There is usually no over-fire nor agitation of material on the surface of the charge, due, no doubt, to the low blast-pressure, which is 24 oz. per sq. in., and to the low smelting-column. In the beginning of smelting operations, in 1906, much trouble was experienced with accretions. The percentage of fine ore in the furnace was large, and high pressures, up to 52 and 56 oz. per sq. in., were used, making work around the charging-doors quite unbearable because of the shower of hot material. Barring down was extremely trying and ineffective. 'Freeze-ups' were frequent. Elimination of a considerable proportion of the fine, reduction of pressure, increased volume of air, and low smelting-column have bettered the running of the furnaces, and have lessened the accretions and 'freeze-ups.' There do not seem to be any radical changes in the operation of the furnaces because of the altitude. The working of the furnaces may be classed as being on semi-pyritic lines.

The following analyses have been furnished by the company, the figures in parentheses being personal estimates:

The specific gravity of the slag is about 3.0, and its temperature on leaving the settler, probably 1100° C. Samples are taken hourly. The average number of daily ore-charges for the four furnaces varies from 170 to 180, equivalent to 600 to 640 tons; about 2.3 tons of ore are smelted per day per square foot of hearth-area. Total hearth-area is 272.5 sq. ft. The degree of concentration is about 5 to 1. All the charges are made on the basis of kilo-weights, the ore weighing 3200 kilos per charge. At present there are two roasting-furnaces of the McDougall type, 18 ft. diam. and 16 ft. high, with six tiers. They handle a small part of the fine ore (½ in. and less), which forms more than 50% of the tonnage mined. The roasters are electrically driven, requiring 3 hp. each, and handle about 65 tons of raw ore, or a total of 130 tons daily. They effect a desulphurization of 75%, roasting ores carrying from 25 to 35% sulphur down to as low as 8%; the calcines weigh 20% less than the raw ore. In starting the roaster about three tons of coal are used for the first six hours in the firebox below the shell. In that time the ore will kindle and burn of its own accord. The ore is fed continuously by means of a plunger-feed from a hopper above the furnace to the periphery of the first hearth. The revolving rabble-arms are water-cooled. No trouble has been experienced with accumulated crusted or lumps of ore, as proper attention is given to their prompt removal. About 5% of flue-dust is made; this passes from the furnace through four separate up-takes to the dust-chamber, where it mixes with the fume from the reverberatory. The sulphur begins to show signs of burning on the secoed tier or hearth, while on the third tier the blue flame and strong sparkling is in evidence. On the fourth tier the ore is quiet, and has an orange heat. The maximum heat appears on the fifth tier, where the last of the sulphur is burning off. On the sixth tier the ore is cooling and is dark except for the white particles of silica. The roasting takes about four hours. The hot calcines are dropped into a hopper, and theue, in 3-ton charge-cars, to the reverberatory furnace immediately in front. No lime-rock is used in roasting.

Apart from discrepancies between raw ore and calcine analyses, and between calcine and slag analyses, are due to the figures, as given, representing different classes of ore. This is due to the fact that the roaster-charge is made up of a mixture of different ores, such as fines from Peña Blanca and Noruega mines, and no separate analysis is made of the roaster-feed. The following are representative analyses:

The discrepancy in several ingredients of this slag is due to the fact that there is a considerable amount of blast-furnace flue-dust introduced into the charge in addition to the calcine smelted.

The reverberatory building adjoins the south side of the blast-furnace and converter building. Despite the forebodings that a reverberatory would not smelt successfully, although this practice in Cerro de Pasco with coarser ore and small furnaces seems to have been followed for years previous to the advent of the American company, the present furnace has been running since the latter part of April, 1908, treating about 3500 tons of calcine per month. The adoption of this system has spelled 'success' and has overcome the difficulties experienced in the earlier operations of the blast-furnaces, at the same time lowering the smelting-costs. The furnace hearth is 19 ft. wide and 60 ft. long, over all. The actual hearth area is 995 sq. ft. Coal is used for fuel; the escaping gases passing to a flue and thence to the dust-chamber. The steel-work consists of 8 in. 18-lb. I-beams (in the newer furnaces these will be 9 in. beams) and 13/4 in. tie-rods, with standard turnbuckles, bracing and passing over the brick-work. No tie-rods pass under the hearth. The stone foundation is filled in with molten slag; above this 2 ft. of silica (95% SiO₂) is tamped in layers of 6 in. at a time. The fire-box is 7 ft. wide and 18 ft. long. The actual grate-area is 117 sq. ft.; the ratio of grate-area to the hearth is 1:5.5. The outlet flue is 4 ft. wide and 5 ft. high, connecting with a flue 5.5 ft. wide and 7 ft. high, which passes to the dust-cham-ber. The skimming-door, which is at the front end of the furnace, is 18 in. high and 24 in. wide. The slope of the hearth toward the matte-tap hole is 1/4 in. in 1 ft. The rise of the arch is 1½ in. in 1 ft., and the height of the interior of the furnace at the centre is 6 ft. 5 in.

Transverse expansion-joints, 2 in. wide, have been placed every 10 ft. in the length of the furnace. There are four of these. The fire-bridge has three 4-in. expansion-gaps. The bridge is 18 ft. 4 in. long and 4 ft. 3 in. wide; the top is 3 ft. above the hearth, and 2 ft. 6 in. above the grate. Air from the converter-blast passes under the cooker-plate. Above the bridge the roof is pierced with 18 check-holes 6 by 8 in., arranged in two rows. From bridge to arch is 3 ft. 8 in.; the arch is made of 12-in. silica brick. The bridge on the grate side, in the new furnaces, will be faced with fire-brick, owing to trouble with clinker adhering to the silica-brick two side-doors, 16 in. high and 18 in wide, will be placed on the fire-box, so that the bridge can be cleaned of clinker. The present furnace has three stoke-holes, 14 in. diam., closed by wheel-doors, which will be replaced by five in the new furnaces. Coal is fed from four hoppers, with 14-in. openings, almost continuously, the flames being nearly white hot. To insure good results a 36-in. electrically driven fan, making 720 rev. per min., producing 2½ oz. pressure at fan, furnishes air through a 2-ft. pipe to an open box set 12 in. below the grate-bars. The fire is 'grated' from time to time, and particularly prior to dropping a charge. Cast-iron doors have been found most suitable to enclose the ash-pit, and are opened only to allow 'grating' and cleaning out of the ashes. The escaping gases at the flue have a temperature of about 1100°C. The condition of the furnace, as regards heat, is judged by watching a silt in the outlet flue from the fire-box platform. It is believed that a deeper fire than the 20 in. of coal now carried on the grate, and higher pressure (only 1½ oz. being now effective at the grates) would induce faster driving. There are four rabble-doors to a side, each 16 in. high and 18 in. wide. Only the two nearest the fire-box are used, and these are to take care of the 'floaters.' The side-walls are made up of 22½-in. fire-brick and 9-in. silica brick. Of the six charge-openings beneath the charge-hoppers, which are fed from the roasters, only two to four are used; the diameter of the charge-opening being 16 in.

Calcine is fed in 9 to 15-ton charges every two to three hours, depending upon the running condition of the furnace. With a 9-ton charge about 800 lb. of CaO, about 1500 lb. of lime-rock as a maximum, is added, according to need. Should there be a scarcity of calcine, fine-dust is also charged up to three to four tons. The charge falls on a bath of 14 to 16 in. of slag and matte, and soon begins to fuse; as the doors of the furnace are closed, very little fine-dust passes to the flue. Skimming is never begun less than one hour after charging, usually after three to five charges, and at least once a shift; it takes from 20 to 30 min. for the process, depending upon the amount of slag. As can be judged from the analysis, the slag is quite fluid, flowing away like water; the long
hearth, high heat, and thind slag effect a clean separation of slag from matte. A matte-trap 4 ft. long, 2 ft. wide, and 18 in. deep, is used just below the skimming-door; from this pot the slag is being run to fill foundations for the new reverberatories, and later will be granulated and washed away by a jet of water passing below the matte-trap.

Matte is tapped according to the needs of the converter; at least four to five ladles are tapped every 24 hr. The matte is run out from the furnace in a semi-circular clay-lined launder, 12 in. wide, dropping into the ladle, which is spotted in a pit close to the furnace. It is customary to keep about 13 in. of matte in the furnace. The matte tap-hole is covered with a 12 by 14-in. cast-iron plate with 2-in. tap-hole in the centre. Fettling of the furnace is necessary about every two months, and takes from 5 to 6 hr.; 95% silica is used. It takes 48 hr. to warm up the furnace. About 35 to 40 tons of coal (nut size, from the washer) are used daily on an average of 110 tons of ore; this means 3 tons of ore to 1 ton of coal. There is 0.44 lb. coal-burned per minute per square foot of grate-area. The degree of concentration is 4½ tons of ore to 1 ton of matte. About 220 lb. of ore are smelted per square foot of hearth-area per day. The following analyses have been given by the company:

The converters are in front of the blast-furnaces. There are 4 stands and 12 shells, of the vertical type. 7 ft. diam. and 14 ft. high over all, having a rated capacity of 10 tons of matte. They are operated by hydraulic power, under a pressure of 300 lb. per sq. in.; air-blast is used at 17 lb. per sq. in. When new, the inside dimensions are 3.5 ft. diam. and 8 ft. high. Silicious ore and clay are used for lining. The lining runs about 70% SiO₂, and carries low gold and silver content. About 1200 tons of silicious ore, and 500 tons of clay are used monthly, for 225 re-linings, about 7.5 tons entering into one lining. A lining lasts about three charges. The matte-ladle has a capacity of 6½ tons of matte when filled to within 6 in. of the top. It is spotted by the crane under the launder of the blast-furnace settler, and about 5 ft. below the matte tap-hole; the launder is 12 in. wide, semi-circular, and clay-lined. The matte is poured while the converter is in a horizontal position. As the shell is turned up, air is gradually admitted below the matte. The first charge is usually 2.5 tons, the 'blow' taking about 22 min.; then more matte is added, after the slag has been skimmed. About 5% Zn and 7.5% Pb are volatilized. After the first charge has been poured, floor-cleanings are added prior to the matte, and no silicious ore is charged. It takes 1 hr. 10 min. from the beginning of the first blow until blister-copper is ready to pour. As much as 1½ hr. is frequently consumed in pouring the copper; it is cast into flat cakes, about 2 by 18 by 24 in., weighing approximately 100 kilos. Sampling is done with a long-handled ladle, which catches the splashings from the pour. Previously the copper was cast in bars 8 in. thick; somewhat wider at the top than at the bottom, and 2 ft. long; drill-samplings of these bars gave unsatisfactory results. The cakes assay 99% copper, 100 oz. silver, and 0.10 oz. gold. About three charges are made per stand per each 8 hr. The converter slag is poured from the ladles into a casting machine, from which the molded slag is water-cooled, sledged, fed to a crusher, and then elevated to the bins above the feed-floor of the blast-furnaces. The slag forms a desirable mechanical and chemical flux for the blast-furnaces. Two 5-ft. clay-nails, electrically driven, grind and mix the converter-lining. The clay is mined in the hill back of the power-house. A compressed-air rammer, taking the same air as the converters, is used for re-lining. Two 40-ton steel cranes handle the matte ladles, converter shells, and the like. They have a 60-ft. span. There are four motors, requiring about 75 hp. Alternating current has not proved very satisfactory, causing delays and expense in burn-outs, due to the variable load. The converter-hoods communicate with a steel-line which passes to the large dust-chamber, together with the blast-furnace dust. Probably 1½ to 2½% of fine-dust is made. The hood ectocations run high in lead. They are usually re-fed to the converter. The converter-dust is cleaned once a month, and the dust is fed to the reverberatory. At 8 a.m. daily the blowing engine is shut down and is thoroughly inspected, taking one half to three quarters of an hour.

The additional plant planned and now under construction will consist of eight McDougall roasters, four reverberatories, and a copper-casting machine. A separate dust-chamber and stack-mouth, 450 ft. above the reverberatory floor, with an inside diameter of 21 ft., will be built for the roasters and reverberatories. This new plant indicates the success of the reverberatories, and will mean that more ore will be handled in the blast-furnaces by diverting all the fine ore to the McDougalls. The total daily tonnage of ore smelted will be 1200 to 1300 tons.

Smelting operations began in July, 1906. From that time until March, 1907, the furnaces ran intermittently, considerable time being lost in freeze-ups. During those eight months 4,800,000 lb. of copper was produced. From March until January, 1908, with a re-arranged system of smelting, the production was 19,000,000 lb. From January 1 until August 1 of the present year, a period of seven months, about 17,000,000 lb. has been produced, July being the best month on record, with 2,700,000 lb. The probable production for 1908, at the present rate, will be more than 33,000,000 lb., and this should be increased next year to between 50,000,000 and 60,000,000 lb. In June, 1908, about 18,000 tons of ore was smelted in the blast-furnaces, requiring 4000 tons of limestone, 6000 tons of converter slag, and
2700 tons of domestic coke. The reverberatory furnace treated 3500 tons of calcine, 400 tons of fine dust, requiring 160 tons of limestone and 1100 tons of coal. The production was 2,400,000 lb. copper. In the beginning of the present month (August) a daily production of 120,000 lb. has been made, and the output for the month will be close to 3,000,000 pounds.

At present there are 900 men employed in the operating and 400 in the construction departments. Of the total 1300 men, 175 are foreigners, chiefly Americans. The native laborers, 'chole,' or half-caste Indians, are not efficient, lacking ordinary intelligence and interest in the work. They serve, however, owing to cheapness and necessity, receiving an average of 75c. per day. Active work in high altitudes is trying, physically and mentally. Every six months the higher class of foreign labor is allowed 10 days respite in lower and warmer regions. The weather at times is very disagreeable, much snow, hail, and rain, but clear days are exhilarating; the nights are cool. The company has built a comfortable club-house for the use of the American contingent. It contains a library and reading-room, bowling-alleys, billiard and pool-room, gymnasium, plunge-bath, and so forth. The boarding-houses, to accommodate the Americans, are run by the company at a monthly deficit. A nominal sum of £5 per month is charged for room and board. The Cerro de Pasco Mercantile Co. operates a large store in conjunction with three others at the coal mines; there is none in Cerro de Pasco. A small hospital, with four or five beds, is situated close to the plant; a larger main hospital, with 50 beds and all modern equipment, is being built at Cerro de Pasco.

The company refuses to give cost data, but the following figures may be considered reliable estimates of operating costs:

<table>
<thead>
<tr>
<th></th>
<th>U.S. Cy.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Coal mined and delivered in cars at the mine, per ton</td>
<td>$1.75</td>

</tbody>
</table>

With the new plant in operation and a new 10,000-hp. electric plant, run by water-power under 600-ft. head, costing $850,000, which will supply mines and smelter and lower costs of copper 1½c. per lb., the probable cost per pound of copper laid down in New York, after deducting gold and silver content, might be 5c. This figure compares favorably with the operating costs of larger plants in the United States, where commodities and freights are less expensive. It might be noted here that the smelter warehouse carries a stock valued at $500,000, which large supply is necessary owing to the unreliability of prompt delivery of freight by steamers and railroad. Freight might take from 25 days to 6 months to arrive in Callao. Under the present management the policy of lowering costs and increasing production will be pursued to the utmost limit.

**Tungsten production** in the United States for 1907 amounted to 1640 short tons, the value being $890,048. The principal tungsten minerals are wolframite, a tungstate of iron and manganese, and scheelite, a tungstate of calcium. Both minerals, like tin ores, occur as a rule in quartz veins cutting rocks containing much silica, such as granite and rhyolite, but some apparent exceptions are found, as for instance, in New Mexico, where hübnerite and a small amount of scheelite occur with pyrite and lead minerals in a vein cutting limestone; and at Nome, Alaska, where scheelite is found in the gold placers in a region of schists several miles from the nearest granite outcrops. The greater part of the American tungsten product came from the mines in Boulder county, Colorado, which reported an output of 1146 tons of wolframite valued at $573,642.74. In California, which was the second State in order of production, the output was in the form of scheelite, as was also most of that from Montana. The total scheelite reported was 414 short tons. Small amounts of tungsten ores were produced in Washington, Nevada, Arizona, and New Mexico. In other countries besides the United States the production of tungsten was notably increased during 1907. The output of Australia (including Tasmania), amounting to 1643 tons, was, however, the only one that exceeded that of this country. Reports of production from South Africa, New South Wales, and the northern territory of Australia show marked increases. Spain, New Zealand, Austria, and Germany, with a combined production during 1906 of 463 short tons, have not made public their figures of production for 1907, but it seems probable that there will be increase. Tungsten deposits, according to F. L. Hess, of the U. S. Geological Survey, are usually pockety, the ores occurring in lenticular masses or shoots in veins. Those occurring at the surface are often quickly and easily mined, and it may then require all the profits made from the first-exposed orebody to find another one. However, the veins carrying tungsten minerals are generally of deep-seated origin.

In Queensland the deposits exposed on the surface have been largely exploited, and the production has, in the face of rising prices, fallen greatly since 1905.
ORE CONCENTRATOR.—No. 900,412. Albert H. Stebbins, Los Angeles, California.

In an ore concentrator, the combination with an inclined and diagonally disposed perforated plate, a stepped or zigzag wall at the upper side of said plate, and riffles extending across said plate from the wall opposite said stepped or zigzag wall so arranged as to direct the material against said zigzag wall.

PRESSURE-FILTER.—No. 500,134. Charles W. Merrill, Lead, South Dakota.

In a pressure filter, the combination with a container, of a grille or grating placed on either side thereof entirely within the same and in such position that when the container is put together with the filter plates in a filter press, said grille will retain a layer of unfilterable matter or precipitate.

PROCESS FOR STOPPING OR SEALING OFF UNDERGROUND FLOWS OF WATER INTO MINE-WORKINGS, ETC.—No. 900,682. Edmund B. Kirby, Flat River, Missouri.

The described process of sealing off flows of water issuing from the earth's crust into excavations made therein, which consists in the introduction into said flows, at any convenient points prior to their points of exit, of any kind of solid matter which is capable of being carried by said moving flows toward said exits and of accumulating and choking up the passages leading thereto.

SYSTEM OF MINE-TRACKAGE.—No. 900,363. Freeman R. Wilson, Jr., Worthington, Ohio.

A track system for a mine cage room, comprising the loaded car track 4 extending from the room doorway to the mine shaft, and a return track extending from the oppo-

side side of the mine shaft to the said doorway, said return track having a down-grade section 5, an up-grade section 7, and thence a down-grade section to the room doorway, and a car hand mechanism for said up-grade section 7, substantially as set forth.

The herein described method of separating metals from their ores which consists in forming a pulp; passing said pulp containing the metals over an oily adhesive substance; and in abrading the surface of said substance by drawing apart the body of the same, and thereby causing some of the mineral particles to adhere thereto, substantially as described.

In a safety brake mechanism for elevators, the combination of guides provided upon the opposite sides thereof with clutch teeth, a car having a head beam, bearing plates vertically mounted upon the ends of the head beam and provided with outwardly extending vertical flanges forming guides, depending bearing portions projecting below the head beam and ears projecting above the head beam, a vertically sliding bar mounted upon the head beam and adapted to be connected with the hoisting cable, spring means for resisting the upward movement of said bar and drawing the same downward when the cable breaks, stays connections between the upper end of the bar and the ears of the bearing plates, rock shafts extending across the car in parallel relation below and on opposite sides of the head beam and journaled in the depending bearings of the bearing plates, dogs upon the outer ends of said shafts to engage the clutch teeth of the guides, a cross head upon the upper end of the bar, crank arms upon the intermediate portions of the shafts, and links connecting said crank arms with the cross head.

RECOVERING SILVER FROM SOLUTION.—No. 901,124. Thomas A. Ross, Selby, California.

Means for agitating value bearing solutions, said means comprising a stirrer-member and a flexible pipe, having its lower end carried by the stirrer-member and freely movable thereby and adapted to inject a compressed fluid into the body of the solution.
COMPANY REPORTS.

GRANBY.

The Granby Mining, Smelting & Power Co., operating in the Boundary district, British Columbia, has just issued a report for the year ended June 30, 1908, which compares as follows:

- **1908.**
  - Copper, lb. 21,126,926
  - Silver, oz. 306,553
  - Gold, oz. 40,153
  - Gross earnings. $3,798,184
  - Charges, etc. 2,435,700
  - Net profit 354,424
  - Dividends 671,000

- **1907.**
  - Copper, lb. 16,410,576
  - Silver, oz. 300,593
  - Gold, oz. 1,324

The price realized on fine copper averaged 19 1/4 cents per pound, and gold $20 per ounce. The net cost of copper, after deducting gold and silver, was 10.31c. per lb. The cost of a ton of ore, including all expenses, was $3.486.

The president, J. Langeloth, says:

"The mechanical devices now in operation, such as hoists, shafts, belt-conveyors, mine-cars, and electric locomotives, are able to handle about 5000 tons of ore daily. The mines shipped to the smelter a total of 355,423 tons during the last year, against 644,549 tons during the previous year. The grade of ore mined was not as good as in the previous year, carrying about one pound less of copper and 10 to 12 cents less per ton of ore in gold and silver. The extraction per ton of ore on the average was 23.42 lb. copper, 0.265 oz. silver, and 0.0454 oz. gold, as compared with 24.43 lb. copper, 0.303 oz. silver, and 0.0503 oz. gold in 1906-07.

"During the summer months a lower grade ore was shipped, due to mining the "gloomy holes" on the surface, which are low-grade and which can not be mined during the winter months. Consequently the ores will average richer in winter and spicing and poorer in summer and fall. The quantity of ore developed by diamond-drilling has been larger than the ore extracted. The total tonnage of Granby and foreign ore amounted to 882,611 dry tons, against 665,915 tons in the previous year, and there were produced 21,126,926 lb. of copper, against 16,405,497 lb. The cost per pound of copper produced, after deducting the value of gold and silver, was 19.24c., against 19.14c. and 8.35c. in the two previous years.

"Almost immediately after issuing our last annual report a most severe panic broke out, and among other disastrous consequences, the consumption of all metals decreased materially, and prices showed a heavy decline. Prices fell off from about 25 cents to close to 12 cents, and showed little recovery during the first six months of the present year, due to the great falling off in the consumptive demand for home trade, which, however, has lately shown improvement, and if this continues, as appears to be the case, it may be confidently hoped that prices will show a further improvement. The enormous decline in the price of copper and the marked influence on the cost by reason of the difficulties with which the smelter had to contend, permitted the declaring of only two dividends, namely, one of 2% on September 30, 1907, and one of 2% on June 30, 1908."

HOMESTAKE.

The annual report of the Homestake Mining Co., just issued, is for the 12 months ending June 1, 1908. In his letter of transmittal, T. J. Grier, the superintendent, states that the Homestake "has long since fully recovered" from the fire that crippled production in 1907. The orebody has been cut at 1500 ft. in a westerly cross-cut from the Elison shaft. At 1790 ft. also the west side of the same shaft has penetrated ore. Evidently the Homestake has not yet been bottomed.

No mention is made of the damage done by the fire, or of the cost to the company, except items showing that $100,000 was borrowed and $250,000 repaid. The yield of gold amounted to $4,717,746, extracted from 1,469,500 tons. This gives an average of $3.261 per ton, as against $3.593 in 1907 and $3.54 in 1906. A dividend of $546,000 is recorded among the disbursements, and a balance of $443,918. Owing to the fire, no comparison with the preceding year can be made. The cost charged against the two sand-plants for the years ending in June, 1906 and 1908, respectively, was $278,000 in one case and $194,000 in the other. This indicates a large saving. The total cost of the slime plant, as indicated by the book three annual reports, is $745,849. This includes a series of settling-vats, as well as expensive pipelines, although the Mineral Point and Monroe mills have been operated by electricity this year, and in 1906 they were charged with $35,000 for fuel, the total charged for fuel at the mills and hoists is practically the same each year, namely, $252,000. In 1908 only 10,000 tons more were milled than in 1906. The tonnage for the last half of the fiscal year ending June 1, 1908, decreased by 176,000, for this period included two months and six days after the fire had broken out. This reduced the yield per ton for the year by 22.6 c. The lower returns for the year just ended are explained by the milling of unusually low-grade ore during the first two or three months following resumption of mining underground.

The statement of accounts is, like its predecessors, not conventional nor complete. In the foundry account we see such items as: Oil, $3,800, and sundries, $25,046.68. Among mining costs, candles have increased from $22,562 to $36,709. Labor in the mine, however, has decreased from $1,655,789 in 1906 to $1,507,144 in 1908, and $184,000 to $146,000.

CONSOLIDATED MERCUR.

The report for the fiscal year ending June 30, of the Consolidated Mercur Gold Mines Co. indicates that operations were conducted at a loss of $43,355 during the first four months of the period under review, and that this loss was wiped out in the last eight months, leaving a net profit of $245,475 for the year. Expenditures were incurred in recapitalizing the Brickyard and Golden Gate mines, and heavy expenditures were made for other permanent improvements. By reason of this work, especially in the mines mentioned, the ore reserves have been increased and prospects are much improved. The new slime plant has proved disappointing on the bauer ores, although it has done excellent work on the oxidized material. The gross output of gold during the year was $446,264, from 238,229 tons, of which 61% was oxidized and 39% was native. Operating expenses were $650,025. The average assay-value of the ore treated was $3.77; the tailing averaging 92 cents per ton. The cost of mining was $1.65; of milling, $1.26; the total being $2.91. The consumption of cyanide was 0.86 lb. per ton and of lime, 0.85 lb. per ton of ore milled. The general manager is G. H. Dern.
A Gasoline-Driven Drill.

While steam is the well recognized power for drilling purposes, there are many localities where fuel and water are so scarce and expensive as to prohibit its use. In many such places the slow and uncertain stop-motion horse-power drill has been resorted to; or, if gasoline engines are attempted they are applied to some sort of tremble-motion machine which allows the drill to take a time-killing rest between strokes. As distinct from all these different make-shifts, the machine illustrated herewith, while intended for localities where fuel or water is scarce, will be found a close competitor of the steam engine. The aim has been to produce a machine as nearly as possible in every respect equal to a steam-driller. In fact, the manufacturer simply takes his well known No. 3 and 5 Keystone Steam Drillers (both traction and non-traction), leaves off the steam-engine, boiler, etc., and, without other change, equips them with gasoline motors and a peculiar and specially devised power transmission.

The engines used on the drilling machines, namely 14-hp. on the No. 3 non- traction, 20-hp. on No. 3 traction, are of the two-cylinder type with the pistons so opposed to each other in the crank that the crank-shaft receives an impulse every half-revolution. In this way one piston counter-balances the other, so that there is practically no vibration to the engine. The crank-shaft bearing and pistons are completely enclosed against dust. The entire internal parts of the engine are conveniently removable through a covered aperture in the engine-frame. This construction permits the greatest possible lightness and strength and allows lubrication to be done by the splash system from a quantity of oil in the crank-shaft pit, thus avoiding necessity for grease-cups or oils for pistons or crank-shaft bearings.

The tendency of the lubricating oil to leak outward through the main bearings of the engine is obviated by a simple check valve. The cylinders and truss of the engine are cast in separate pieces so that in case of possible injury to any one of them it can be replaced at small expense.

The engines are governed perfectly by a reliable fly-ball type of throttling governor, driven direct by the engine without belts or perishable devices, and will maintain a uniform speed at all times. The constant speeds of the engine can be changed instantly at the will of the operator and will remain exactly where left. It is impossible for the engine to get away from the control of the governor. Cylinders and frame are of cast iron, which has been found best suited for this purpose. The cylinders are thoroughly water jacketed to prevent overheating, eliminating danger of premature ignition, and burning out of valves. The pistons are of iron thoroughly ribbed and braced to prevent unequal expansion and contraction, and fitting close to the cylinders. Valves are made of special steel resistant to the oxidizing effect of the gases. A set of these valves should give years of service without renewal.

The area of valve openings and ports is at least one seventh the area of the piston. The cam lift the valves more than one fourth the valve diameter. With such large areas and openings the engine will operate at piston speed of 550 ft. per minute, giving the highest mean effective pressures. Inasmuch as the nominal rated horse-power of the engine is based upon piston speed of 1000 ft. per minute and take in full charges, the engine is capable of developing much more than the nominal rated horse-power at these higher piston-speeds.

For ignition a non-vibrator high tension coil is used. The timer is very simple, and cannot be easily disarranged. The working and contact parts are larger than in the ordinary article. All wearing parts of the timer are made in duplicates, and are inexpensive. Should the electric contacts become worn, provision is made for taking up this wear from the outside of the device in a few moments without disturbing any other adjustments.

There has been selected the most efficient dry cell on the market, and each machine is equipped with two sets of five cells each, arranged in a convenient weather-proof box. Anyone of ordinary intelligence can remove the worn cells and replace new, should it ever be necessary. Inasmuch as these cells are used only in starting and operating the cylinders, rings made of special hard iron, about twice the thickness of similar rings in other makes of engines. Valves are made of special steel resistant to the oxidizing effect of the gases. A set of these valves should give years of service without renewal.
have so-called spark-coils for intensifying the electric current to produce a sufficient spark at the electrodes or sparking points to ignite the gases. Practically every other gasoline motor uses a coil having a vibrator or interruptor in the primary circuit. This vibrator requires quite frequent adjustment. We have been successful in our experiments with spark-coils, dispensing with this vibrator, and equipping all machines with a special coil hermetically sealed in a box, so that it is impossible for it to become damaged or disarranged.

Each motor is provided with two sets of ignition plugs. It requires but an instant to change from the set in use to the reserve plugs. The sparking points of these plugs are made of a metal that is unaffected by heat.

The machine is equipped with two 49 gal. galvanized-iron tanks, spaced almost entirely over the motor, in such a position as to give the proper gravity feed of the gasoline to the carburetor and cooling water to the jackets of the engine. Forty gallons of gasoline is sufficient to run the engine under ordinary loads for a period of 30 hr. About five or six gallons of gasoline is required to run the engine 10 hr. without load. Then, for every horse-power of load, one additional gallon of gasoline per 10 hr. will be required. This rule is subject to slight variation, for the efficiency of the engine increases with the load. For instance, the engine will probably deliver 20 hr. for 10 gal. of gasoline, or 2 gal. per hr. The usual load will be about 7 or 8 hp., and the average consumption of gasoline from 13 to 14 gal. per 10 hr. The evaporation of water is not at a greater rate than 2 gal. per hr., and one tank should be sufficient to cool the engine for 20 hr.; however, the water tank should be kept on half full at all times. Any kind of water may be used for this.

This machine is provided with a regular automobile-type front axle and steering device. This axle is much stiffer than the old-style axle. The steering mechanism is of the regular worm and sector self-locking type, and is controlled by a hand-wheel placed in the rear of the machine, and is operated nearly as easily as that of a large automobile. One and a quarter revolutions of the steering-hand-wheel is sufficient to throw the steering wheels from straight ahead to the extreme right or left. This machine will turn in a much smaller circle than the old style.

Makers of well-drilling machinery have been trying for twenty years to adapt gasoline engines to the operation of this class of machinery. All attempts have been unsuccessful, because of the lack of a practical and dependable graduated reversible power-transmission. We have perfected a device for this purpose. It consists of a combination friction driving disk and fly wheel on a motor and a driven wheel on a transverse transmission shaft. On this shaft, at one end is placed the pulley which drives the drilling mechanism with a belt, and on the other end of the shaft is placed the traction driving gear. This transverse shaft rotates in large slidable, hardened-steel ball bearings, arranged to engage or disengage the drive-wheel with the friction driving disk. It is understood that the driven-wheel is arranged to slide entirely across the face of the driving disk, and in that way the speed graduation from '0' to 'high speed' or 'reverse' is obtained, that is, in sliding this driving wheel from the center toward the periphery, to the right, gives all speeds from '0' to 'high speed' ahead, and from the center to the periphery, to the left, gives the graduated increasing speed backward.

The friction driving disk has a hard-wood filling, which is put in on the end-grain, and is arranged to wear down 2 in. before needing renewal. It is our belief that this filling will last as long as the machine; but if it should worn down it can be replaced by anyone, in the field, by nailing a new layer over the friction-surface and turning it down to the proper shape.

In operation the motor runs constantly in one direction at a predetermined and governed speed (which may be at will anywhere between 250 and 500 rev. per min.), and at such speed it will produce any power placed upon it, from no load to full load, as required.

Commercial Paragraphs.

The Halmon-Fielding Engineering Co., Denver, has received the contract for a 12,000 cu. ft. blower for the U. S. Mint, at Denver.

The J. M. Dodge Company is the new corporate name of The Dodge Coal Storage Co., a subsidiary company of the Link-Belt Company.

The John A. Roebling Sons Co. has lately moved its San Francisco office to its new five-story building at Polk and Hawthorne streets.

Wellman-Selver-Morgan Co. announces that its San Francisco office has been moved to the Marvin Bldg., 24 California street. W. Q. Wright is manager.

The A. S. Cameron Steam Pump Works, New York City, has added a condenser department to its already immense organization, and announces that it is prepared to build jet, surface, and barometric condensers. The Company has a well deserved reputation for reliability and character in its pump business, which should recommend it to prospective users of condensers.

The Redon Iron & Locomotive Works, of San Francisco, has obtained a favorable decision in a suit brought against the Western Engineering & Construction Co., and the Central Gold Dredging Co., of Oroville. The suit was for infringement of patent on the use of the revolving seeder with spray pipe, constituting the washing apparatus on modern dredges. Judge Van Fleet of the United States Circuit Court gave this decision on October 27.

The Colorado Machinery & Supply Co., Denver, expects to occupy its new quarters at 1650-52 Wazell street, about November 10. The building is to be 50 by 110 ft., two stories and basement, and will contain the office and sales room. The machine shop and warehouses are at Walnut and Seventh streets. The Company carries a large stock of new and second-hand machinery and has secured a number of important Eastern agencies for boilers, pumps, and other accessories.

The Edge Computer is an ingenious mechanical device recently put on the market for computing the weights of plates and structural shapes, of any length, without multiplication or reference to books or tables, and with an astonishing degree of accuracy. The weight is obtained by one setting of a revolving disc, and the operation is so simple that no experience is required. The appliance is manufactured by the Edge Computer Sales Agency, New York, and will be supplied by the Mining and Scientific Press.

Publications Received.

The Cement Resources of the Black Hills. Bulletin No. 8 of the South Dakota School of Mines, Rapid City, South Dakota.

This is a handsome volume, giving brief biographies of leading technical men making London their headquarters.

In matters of classification and geology this book is essentially British; the chapter on determining the value of fuels is excellent, as far as it goes, but it stops short of that completeness demanded of the coal-mines value in America; but the review of methods of boring is well worth the price of the volume. While more elaborate descriptions of boring operations exist, we are unaware of any collection of data so full as this concerning the many recent systems and wrinkles in drilling which have been brought out on both sides of the Atlantic. The chapter on surveying boreholes is also clear and comprehensive.

EDITORIAL.

FROM SALT LAKE we have received an important letter describing a recent invention for condensing smelter fume. This letter appears under Special Correspondence; it is written by Mr. Courtenay De Kalb, who is visiting the Bingham mines in our interest.

WESTERN MEN are aenstomned to associate scientific sampling with the name of Brunton; therefore it is with particular pleasure that we publish a letter on this subject from Mr. D. W. Brunton. Among the improvements in metallurgical practice during the last twenty years, the invention of accurate machines for sampling is one of the most noteworthy, for no work in mine, mill, or smelter can be cheeked intelligently without exact knowledge of the contents of the ore.

FIFTEEN CENTS for copper before the end of this year is confidently predicted among the metal brokers. Most of the large producers have disposed of their output up to January, and even into February. The Pennsylvania Railroad Company has signed a contract with the Westinghouse Electric and Manufacturing Company for $5,000,000 of material to be used in electrification of its railway system. It is estimated that $30,000,000 will be expended in similar work on the Pennsylvania and its branch lines. This indicates an outlet for copper.

DURING the 12 months ended June 30 the yield of gold from the mines of the Transvaal was £28,514,311, as compared with £26,640,490 in the previous year. The total profits for the eight months ended on August 30 was £7,852,454, and the dividends £4,262,672, as against £3,365,584 for the corresponding period of 1907. This improvement is credited to the increased use of tube-mills, greater efficiency of native labor, and better results from the deep-level mines.

IT IS DANGEROUS to christen a mining camp for mineralogical reasons until scientific evidence is available. Telluride, in Colorado, is a poor place to get specimens of telluride ore, and at Cuprite, in Nevada, you can get stains of copper carbonate more readily than the sub-oxide; as also at Malahite, in Huerfano county, Colorado. There are 13 post-offices in the United States named Galena, from which the wide distribution of lead ore may be inferred. Cobalt proved no misnomer, although it was silver that made the cobalt ore commercially valuable. Alumite is aptly named; only everybody does not know what alumite is. Tin City and Cuprum are names recalling "the saddest words of tongue or pen," for they refer to the confident hopes of a mineral development that
Analysis of the Election.

Mining engineers are citizens and as professional men they ought to be among the most intelligent of those having the rights of a citizen. A presidential election in the United States is an event of worldwide interest, as throwing light on the development of representative government in the most progressive of democratic countries. To those of our readers who live in America we can give but little new information, but to Americans and the friends of America in those distant lands to which this journal goes, we hope to offer comment that may prove interesting. Now that the dust of the campaign has subsided and the election returns have been analyzed, there are many features that stand out clearly. Mr. William H. Taft won because he was regarded as a man of good sense and strong character, he represented the dominant party, the party that is identified with the protective tariff, and the business interests of the country; he was also an exponent of the policies of Mr. Roosevelt, a President to whom it has been given in unusual degree to express the national spirit. For 12 years Mr. Bryan has been the safety-valve of popular unrest, he has advocated many reforms, not always consistently, and as he has led the Democratic attack on the Republican tariff, he has inevitably intimidated the protected interests and the large number of manufacturers who have grown rich under protection. But, on the surface, the tariff did not cut a big figure this time. Labor did. The leader of the labor organization supported Mr. Bryan, and an appeal was made to the labor vote, the chief effect of this move being to frighten the employers of labor without overcoming the idea of most laboring men that Mr. Taft's election would stimulate industrial activity and thus give them a better chance of employment. In other words, the average citizen voted for the candidate and the party whose administration seemed most likely to bring about a period of industrial prosperity, at least temporarily. Whether national or civic ideals are identical with prosperity in business affairs is a point it would be a waste of time to discuss. Most people agree with the British statesman who said that he would rather help the people to eat bacon than to read Bacon. We do not accept that dictum, but others do.

Apart from the victory of Mr. Roosevelt's nominee and the failure of the thrice-nominated Democratic orator, the most important feature of the election was the success of Mr. Charles E. Hughes, the Governor of New York, who was re-elected. This result is immensely encouraging to those who believe in the future of American civilization. A university graduate, and an accomplished lawyer, he became in 1905 the counsel for the legislative investigation that revealed the corrupt methods of the big insurance men, and he did his work so fairly and so unflinchingly that he was elected Governor in 1906. Since then he has given New York an excellent administration, refusing to take orders from the political bosses, vetoing measures he deemed unconstitutional while advocating reforms successfully. He has been safe and sane, he has exhibited integrity and intelligence, he has proved fearless and forceful. Although opposed bitterly by the party bosses, he was re-nominated and has now been elected in the face of an opposition that combined all the sinister influences within the State of New York. The antagonism of the machine politicians and the appeal of the Governor over their heads to the sound sense and good heart of the people of his State, has ended in the complete rout of the allied villains of low politics, special privilege, and legislative corruption. Governor Hughes is a true democrat; he has taught the plain people that they are responsible for bad government; he has shown them how to get good government. Nothing in recent years can so hearten the believer in the successful outcome of this great experiment in representative government as the late events in New York. And there are other encouraging signs. At Denver the Judge of the Juvenile Court, Benjamin B. Lindsey, who has done splendid work in the reforming of children, has been elected, as an independent, in the teeth of opposition from both the regular political parties. In San Francisco the most interesting event was the election of the Judge who has presided in many of the graft cases. The choice lay between a judge who was not judicial in temperament but honest in character and another judge who was—a plain crook. It may seem strange that the result should have been in doubt. But it was. All the special interests, dominant corporations, predatory politicians, municipal thieves, and others endangered by the investigations of the graft prosecution joined hands to defeat the honest judge; but he was elected. Incidentally, it will not be improper to point out the absurdity of the method by which judges are chosen; it is anomalous for a
judge to have to go before the voters at a time when he is trying cases, the issues of which have eft the community in twain. However, all is well that ends well. This applies to Mr. William R. Hearst, who is also ended. His rag doll of an Independence party has been practically wiped out. It cut no figure at all in this election. But Mr. Hearst managed to get a great deal of pleasant notoriety by reading letters proving that the agent of the Standard Oil Co. had bribed sundry senators and congressmen. As these letters must have been stolen, they suggest the character of the methods adopted by enterprising newspapers. While the exposures killed the political life of the men implicated, they did not affect the outcome of the election. One result is plain: The influence of blatant journalism is gone. Most thoughtful men are glad of it. In California the Taft wave carried with it into office the usual flotsam and jetsam of needy politicians and pliant tools of corporate corruption, but here, as in Colorado and in other States, the scratching of tickets proved that voters are beginning to think for themselves. The man who votes a straight ticket is a bone-head. It is one of the encouraging signs of the times that a big proportion of voters nowadays exercise the privilege of choice, so that a bad man on a good ticket may be defeated by a good man on a poor ticket. Thus Hughes was elected in 1906 when all the other nominees of his party were beaten by the Democratic candidates. Thus Democratic governors have been elected in States that gave Mr. Taft a big majority over Mr. Bryan. This evidence of individual thinking is a cheerful sign; another is the adoption—in several States—of the direct primary, with election of senators by popular vote. On every hand that oligarchy of corruption, the political machine, is being attacked successfully. Thus representative government develops.

**Metal Markets.**

As was anticipated eight or ten months ago, the metal market has revived notably, and purchases are now being made by manufacturers, who in turn are commencing to receive orders in larger volume than at any earlier period of the year. It has been remarkable what caution has been exhibited, despite cheap money; proof has not been wanting that while money was available for the best investments, it could not be had at any price for new enterprises, and especially not for speculative undertakings. During the three weeks preceding the election the East was fairly confident as to the result, but no one was prepared for a victory so decisive, and since the country has spoken so clearly, confidence is returning, and this is helping the metal trades. The position of copper, intrinsically, has been good since early this year, because the stocks accumulated during the panic had been fairly well absorbed, and the large buying from Europe had shown that with the materially reduced production conditions would soon improve. But American buyers, for reasons above stated, were not able or not willing to avail themselves of the low prices then ruling, and later on they feared that when production increased there would be no market for it. All this has proved a blunder, for not only are there no stocks here, but whatever is produced goes into consumption as soon as it is in a marketable state. It is true, abroad the visible supplies have been increased to nearly 60,000 tons, but, far from this being a bad factor, we believe it is a good one, as these are the only reserves existing, and they are easily financed by a number of people, so that at no time shall we have to fear that they will be dumped on the market suddenly, as might happen if the stocks were concentrated in one or two hands. Europe is taking enormous quantities of copper. The consumption over there must be phenomenal, and now that the turn has come here we find also that our home consumers cannot get enough, and much larger business would have been done had prices not advanced so quickly. By this we do not mean that the end of the present movement is in sight. On the contrary, it looks now as though we would soon reach a stable 15-cent basis: this will be a boon to the mining interests that for the last eighteen months have struggled hard to make both ends meet. The outlook is certainly encouraging, and a great many new enterprises will undoubtedly now be started and will consume a great deal of copper. We refer elsewhere to the decision of the Pennsylvania Railroad to have its new New York branch electrified, commencing at Newark. Other railroads will no doubt soon follow. It may interest our readers to learn that the country most advanced in electrolyzing railroads is Switzerland, where about 25 per cent are actually so driven, mostly by power generated from water.

Consumption of lead during the summer months was extremely good, and the large accumulations had nearly all been disposed of, but prices having been pushed ahead too fast, a reaction set in during last month, when the demand for white lead fell off somewhat, and in consequence there was a reduction in the price from 4.60 to 4.30 cents at New York, but this will soon again be overcome, as there are more buyers than sellers. What is weighing on the market is Missouri lead, of which there is still some accumulation. Now, however, that the electrical industries will take larger quantities, these available stocks will soon be worked off. Spelter has remained behind in a most trying way, and during the first eight months of the year ruled from about 4.30 to 4.50 cents at St. Louis. This was a deplorable state for the smelters, who could not secure sufficient orders, except by paying for the zinc contained in the ore on the basis of 5 cents, a most unprofitable operation, as will be seen. Still, the low-grade ores from Colorado, Utah, New Mexico, and old Mexico left hardly anything to the miner after freight and treatment charges had been paid, even if he realized 5 cents. With much better buying on the part of galvanizers, prices have now come up to about 4½ cents and are likely soon to be over 5 cents, which will stimulate the production of ores and place the industry on a more settled basis. The iron and steel situation is mending from week to week, during the last fortnight large orders have been received, which will enable the mills to increase their output.
BY THE WAY.

*For the last two years the English people, if one might believe the sensational press, have been living in terror of something worse than the perennial French invasion, which only last year blocked the plan of a Dover-to-Calais tunnel. Is England disappearing? This is the question the London householder has supposedly been asking himself daily ever since July, 1906, when the Sphere, in a startling article, produced evidence to show that, while Britannia still ruled the waves, Ocean, the might monster, was silently achieving his revenge by destroying England herself. The cliffs at Dover and elsewhere were tumbling into the sea. Even in the memory of living men there were startling changes in the coast line. Was this silent destruction going on at a more rapid rate? Was the nation helpless before the forces of nature? These were the questions the Sphere suggested, with that unfailing result of every public outcry in England—the appointment of a Royal Commission on Coast Erosion, the Liberal Administration thus proving early in its career that its zeal for the safety of the King’s subjects entitles it to their grateful suffrages.

The Commission has sat and done its duty as England expected it to do, and so thoroughly as to prove beyond cavil both the wisdom of the Liberal party and its own recognition of its sacred responsibility. In no less than 1034 pages it has reported its conclusion, which has enabled a whole country to breathe again—England is not vanishing. Tremendous as is the battering force of the sea; great as are its victories; astounding as are the changes in harbors and coasts since the days of the Armada; enormous as are the masses of rock and earth that daily fall into the water, the “tight little island” is not decreasing. Imperialists, with horrifying visions of a really ‘little England,’ may sleep again, and the rate-payers who feared an increase of at least a shilling in the pound to provide breakwaters and bulkheads, are now confident that they will, after all, be able to send their children to a year’s ‘finishing’ in Switzerland. And the Premier, in the midst of his grave cares of state, has been heard to say, according to report: “Well, there’s one thing they can’t accuse me of; England isn’t disappearing from the globe in my Ministry.” More than that, he can “point with pride” to the Commission’s report and say—after the manner of our own Republican party: “See, under our fostering Liberal care, England has not only grown better morally, spiritually, and financially, but has actually added, with God’s help, it is true, at least six acres of land to the entail of England, Scotland, and Wales.”

For this is what the Royal Commission has discovered. The summa summarum of its findings is that destruction by the sea and construction go hand in hand; briefly, that the constructive policy of the sea, as all such policies should, is winning in this contest of the ages. It found that there was plenty of truth in the Sphere’s assertions; that, in fact, more striking and more alarming losses could be recorded than it had cited, but that the Sphere had overlooked the steady gains made by the land from the sea. The shifting sands do not disappear altogether, and are not lost forever. The process is clearly illustrated by the changes at the two lighthouses of South Foreland and Dungeness, near Dover. The former is on the cliffs, and near it the loss of land averages fully two feet per year. At the Dungeness Light precisely the reverse has happened. According to the records of Trinity House Corporation, this spit of land has grown out into the sea at the rate of three yards annually from 1797 until 1850; from then until 1871 at the increased rate of three and one-half yards, and since 1871 at nearly the old speed of three yards. Three times during the nineteenth century, the records show, was it necessary to move the lighthouse nearer to the sea because of the constant accretions of a gravel-like rubble.

At Spurn Head, at the mouth of the Humber, the process is even plainer, for it is to this point that the sea brings the lighter materials it has torn from the Holderness coast. Here the growth per year is as high as six yards—double that of the Channel coast—and it is steady and certain, despite the frequent alterations in the outline of the newly-made land. In protected harbors, too, the increase is constant, owing to the deposits of soil brought down by the rivers, and to matter carried in by the tide as a result of destruction at other points. As soon as the process has gone far enough the newly-made land is fenced or docked in and is at once available. In the Wash the great fans have been entirely created, in this manner, since the first breakwaters were constructed there in the seventeenth century by a Dutch engineer, Vermyniden. Indeed, after a careful comparison of the various coast-surveys of the last thirty to fifty years, the Commission is satisfied that the loss has been only about 760 acres in England and Wales, while the gain has been seven times that figure. For Scotland the gain has been a little less: in Ireland the ratio is about the same.

Britannia’s conquest of the waves is, therefore, thoroughly secure. The Englishman who reads with alarm of such a town as Dunwich, now a mere village, while the city of twelve churches, once a bishop’s seat, lies under the ever-approaching sea nearby, can comfort himself by repeating that, for every acre lost, seven are gained, and that new towns may spring up as the old ones disappear. His fears for the abiding place of his descendants of the twenty-fourth century are stilled. But the rate of growth of the island is still too slow, we fear, to lend itself to dreams of a greater England in the North Sea. During his lifetime Mark Twain will continue, when he sets out for a morning walk anywhere in England, to be haunted, as he has told us he now is, by the fear that if he is not careful he will fall off the edge into the water. To quote Davidson:

“Where argosies have wooded the breeze,

The simple sheep are feeding now:
And near and far across the bar

The ploughman whistles at the plough,

Where once the long waves washed the shore

Larks from their lowly lodgings soar.”

*Re-printed from the New York Evening Post
Personal.

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

Arthur Winslow is here.

COURTENAY DE KALE is at Salt Lake.

GELASIO CAETANI is at Tredwell, Alaska.

P. J. H. Merrill is now at Nogales, Arizona.

J. Parke Channing is at Copperhill, Tennessee.

P. L. Bosqui has returned from Goldfield, Nevada.

P. W. Bradley has returned from his Northern trip.

W. A. Heywood has returned to London from Chile.

A. E. Fifebrace left London for Chile on October 23.

Edward Simpson has arrived in Tacoma from Dawson.

A. G. Shackleford, of Juneau, was in San Francisco recently.

Hugh F. Marriott has returned to London after visiting Canada.

John E. Williams was at Los Angeles and is now at Pittsburg.

Hiram W. Hixon sailed for London from Philadelphia on November 7.

Walter Pethridge has returned to London from Okotsk, Siberia.

Allan H. Rogers is going to examine the Braden copper mines in Bolivia.

Arthur S. Dwight is examining a copper mine in Shasta county, California.

P. L. Slocom, of Pittsburg, has recently been at Parral and Chihuahua, Mexico.

Donald B. Gillies, president of the San Toy Mining Co., is at Chihuahua, Mexico.

C. W. Whitley, the Salt Lake manager for the A. S. & R. Co., was at Reno this week.

R. S. Boysford has returned to London, after having paid a professional visit to Chile.

Evelyn W. Stimson has returned from examining mines in Sierra county, California.

J. Langeloth, of the American Metal Co., has returned to New York from British Columbia.

Edwin J. Watson, of the Yukon Basin Gold Dredging Co., has returned from Dawson to Berkeley.

C. Fred Thomas, for many years manager of South Crofty mine, in Cornwall, has sailed for South Africa.

G. B. Jacobs and Julio Posada, mining and metallurgical engineers, have opened an office at Chihuahua, Mexico.

In Poland, John Crandall, manager for the Dolores Mines Co., Madera, Chihuahua, has returned to the property from New York.

Henry F. Collins has resigned as manager of the Cerro Muriano mines, in Spain, and is now at Crimins, in Cornwall.

Charles A. Pringle, manager of the Calera mine, at Jédro, Chihuahua, Mexico, has returned from a visit to the United States.

Orlando M. Palmer has moved his office to 71 Broadway, New York, where he will have quarters jointly with Mr. Hammond.

T. Lane Carter, of Johannesburg, spoke to the mining students of the University of California on the mining and metallurgical practice of the Rand.

Obituary.

H. P. Seale, assistant manager of the Mt. Morgan mine, Queensland, died in September. He was only 36 years old, a native of New South Wales, and a graduate from Sydney University. A few years ago he visited the United States in company with G. A. Richard, the manager of the Mt. Morgan, and both of them made many friends.

General Mining News.

ALASKA.

Dispatches from Dawson indicate that the Bear Creek dredge was still running the last week in October and that four drills were working night and day. The frost has been heavy and it was with great anxiety that the rifles were kept clear of ice. Fred Rothschilde and Charles Mass, manager and superintendent, have gone "outside." Harold Brown is in charge. —The famous Barnette-Causten case has been settled out of court, but the exact terms have not been made public. The whole controversy hinges on an agreement between Barnette and Smith on one side and J. H. Causten on the other made on August 6, 1891, whereby the latter furnish Barnette and Smith the money to carry out a scheme to establish a trading post at what is now Fairbanks. Barnette later purchased the interests of Smith and has since made a success of the original and several other ventures, among which are the Fairbanks Banking Co. and the Gold Bar Lumber Co. Causten claims that the agreement of 1891 was a partnership contract, and that under it he is entitled to a third interest in the enterprises. It is believed that by the terms of settlement he received less than $40,000. —Two new beach lines have been discovered near Fort Davis, three miles southwest of Nome. They lie between what was formerly called the second and third beach lines, the bedrock of one being at the same elevation as the old third beach line, but divided from the sea by rising ground that is higher than anything found between tidewater and pay-gravel in other places. The second beach line pans from 7c. to $1, while the third runs only 2 to 5c. —Frank Kornans has returned from Seattle to Valdez and brought with him more than $180,000 in gold dust. The result of the season's operation of his hydraulic mine in the Nizina region, far up the Copper river. He stopped operations on September 1, but says he could have continued longer if he had had men to work. —The Burks steam conveyor, on No. 21 Below on Hunker, has shut down for the winter, after a successful season. The conveyor dugs out an open-cut 140 by 100 ft. working thawed ground and skimming along the edge of the frozen ground. The depth there is 27 ft. The company plans to thaw some of its ground. A team will make one round trip per day between the conveyor and the place where the wood is cut.

ARIZONA.

GILA COUNTY.

(Special Correspondence.)—The Arizona Commercial Co., at Globe, has resumed work on the old incline shaft of the Blackhawk mine. Preparations have been in progress for some time to open an intermediate level below the fifth level, at a depth of about 450 ft., which will correspond with the 450-ft. level of the Great Eastern mine. The vein at that level in the Black Hawk property is 25 ft. wide and a drift will be started toward the west on a face of 75°. —The Eureka shaft, nearly 1000 ft. west of the old workings, is down 55 ft. below the 600-ft. level. The work is in well mineralized rock, showing some carbonates of copper, and the work for the past week has developed a better flow of water. The Black Hawk vein carries the best ore on the foot-wall and it is probable that the Eureka shaft has not yet penetrated the vein far enough to develop payable ore. At 700 ft. which will be reached near the end of the month, another level will be opened and a crosscut started toward the vein. The pump will soon begin to drain the Black Hawk workings and work will be resumed, sinking below the present water-level at the old shaft. —Good sulphides have been struck on the 1200-ft. level of the Mallory mine. The discovery of the new vein was made in the west drift. Phoenix, November 7.

ISHAVALY COUNTY.

The large water-tank formerly used by the Santa Fe, at Kingman, has been taken down and will be erected at the Black-Metal mines three miles south of that town. —George Johnson and Fred Stull, of Chloride, have gone to the Treasure Hill district, where they will do assessment work on the Nora mine, formerly the Mocking Bird. This mine has been one of the rich mines of that vicinity and the miners expect to take out enough ore to pay them well while doing the annual work. Last year nearly one thousand dollars worth of ore was taken out while doing the work.

Operations are to be started at the Nighthawk mine, at Layne Springs. The mine is under bond to the Nighthawk Mining Co., of which Thomas M. Purman is general manager. —The shaft of the Golden Gem mine is now 530 ft. deep and at the 524-ft. mark cut a body of 10-oz. gold ore which seems to be a promising vein. A depth of 600 ft. will be made before cross-cutting is started. O. F. Kuener is superintendent.

YUMA COUNTY.

Shinking has been temporarily suspended in the shaft of the Big Stick Co., in the Santa Maria district, on account of striking water at the 250-ft. point. A pump is being put in at the 200-ft. level. —Work will be resumed on the construction of the mill at once, and it will be turning out bullion and concentrate soon, as the intention now is to rush the work to completion. The Big Stick group, comprising 12 claims, is 20 miles northwest of Date Creek station. —The Clara Coa. G. & C. M. Co. has secured the services of James Stirling to make a complete geological and topographic survey of its property in the Santa Maria district. Three shifts are at work in both the No. 1 and 3 shafts, and the adit on the Morro claim is now in 200 ft. A smelter is to be built at once and five carloads of machinery have already been shipped from Globe. George Mitchell is general manager.
